eAppendix. Discordance Sensitivity Descriptions

Five concordance sensitivities were examined. The first two sensitivities considered the upper and lower 95% confidence bounds of the 0.5-SD threshold. The lower 95% confidence interval bounds criteria was <0.67% for office visits and <0.46% for hospital stays. The upper 95% confidence interval bounds criteria was <0.83% for office visits and <0.57% for hospital stays. Third, a “care setting” sensitivity considered that some general internists spend no time in the hospital setting. Seventy two percent (72.3%) of 15,783 clinically active general internists who completed ABIM’s practice characteristics survey as part of their MOC registration during the study period spent time caring for patients in the hospital. For this sensitivity, the percent concordant was set to 72.3% (rather than multiplied by 100%) if a condition category was considered congruent with the hospital stays percentage but discordant with the office visits percentage. One minus this number was used to compute the percent discordant. Fourth, the “Hospital stay data periodicity sensitivity” considered the sensitivity of only including 2010 NCHDS data rather than data from the full 2010 to 2013 sample period. In this sensitivity, the 2010 NHDS data was replaced by NHDS data from 2007 to 2010. Five, the “non-surgical stay” sensitivity excluded hospital stays invasive surgical procedures. After these procedures were excluded, the hospital data included an estimated 19,489,702 admissions compared to 26,915,838 in the base case. These procedures were identified using the Surgery Flag Software Version 2 produced by the Healthcare Cost and Utilization Project (HCUP) (see <https://www.hcup-us.ahrq.gov/toolssoftware/surgflags> for software and documentation).
