For each alternative sequence, the cloned sequence is given first with the GENBANK accession number assigned to the cloned version of the calcium channel or associated subunit. Nucleotides and three letter code for amino acids are given for the region containing and surrounding the alternative sequence with the number of the starting nucleotide in the clone given. If the cloned sequence contains a region not found in other alternative sequences, these nucleotides and three letter codes are shaded green. Transcriptosome sequences are identified by the name given in Aplysiagenetools.org as these sequences have not yet been submitted to NCBI. In some cases, the sequence is entered in reverse orientation and this is noted, as well one of the alternative sequences was only found in an earlier database and this is also noted. These earlier databases are still publically available at Aplysiagenetools.org.

If the transcriptosome sequence contains a region not found in the clone sequence it is shaded in red. If we have confirmed the transcriptosome sequence by PCR it is noted in red text. The single letter codes for the cloned and alternative sequences are shown underneath. The order of alternative sequences corresponds to Fig. 1.
