A. Lay Summary (Max. 200 words)

Herpes zoster, also known as shingles, is a frequent skin infection caused by reactivation of varicella zoster virus (VZV), which lies latent in the sensory ganglia after the primary infection chickenpox. Reactivation of the virus occurs when the immunity towards VZV wanes below a certain critical level. An increased risk of herpes zoster is thus observed among patient with immunosuppression, including those with inherited immunodeficiency and immunosuppression induced by drugs (*e.g.* chemotherapy), radiotherapy, or other disease (*e.g.* human immunodeficiency virus [HIV] or cancer).

Psychological stress may result in suppression of the immune system and thus possibly an increased risk of herpes zoster. However, data from large epidemiological studies on psychological stressors as risk factors for herpes zoster are sparse and conflicting.

Using data from the UK Clinical Practice Research Datalink (CPRD) and Hospital Episode Statistics (HES), we will investigate whether individuals diagnosed with herpes zoster have more frequent history of psychological stress than individuals without zoster, including partner bereavement, depressive disorder, anxiety disorder, and stress or adjustment disorder. We will explore the impact of recentness and severity of stress. Data will be published together with results from parallel analyses conducted on Danish data. The study is a health research study.

B. Technical Summary (Max. 200 words)

We will use CPRD and HES data to conduct a case-control study of the association between psychological stress and the risk of herpes zoster.

We will identify all adults with a first-time diagnosis of herpes zoster between 2000 to 2014. We will use incidence density sampling to select four controls per case matched by age, sex and practice. The date of herpes zoster diagnosis will be considered the index date for cases and their matched controls.

We will identify history of partner bereavement, depressive disorder, anxiety disorder, and stress or adjustment disorder prior to index date. We will categorise bereavement according to whether the partner death was foreseen, as measured by the age-adjusted Charlson Comorbidity Index and codes indicating terminal disease. For the psychiatric diagnoses, we will categorise severity as severe (requiring inpatient admission), moderate (requiring referral to other mental health service) or mild (remaining patients) based on healthcare records within 90 days before index date.

Using conditional logistic regression, we will compute odds ratios with 99% confidence intervals for the association between each psychological stressor and herpes zoster adjusting for risk factors for herpes zoster. We will examine the robustness of our results through several sensitivity analyses.

C. Objectives, Specific Aims and Rationale

The objective of this study is to use data from CPRD and HES to examine the association between various psychological stressors and the risk of herpes zoster. Specifically, we will examine the risk

of herpes zoster following partner bereavement, depressive disorder, anxiety disorder, or stress or adjustment disorder, focusing on the recentness and severity of these stressors. The results from our study will contribute to the understanding of the epidemiology of herpes zoster and may confirm the presumed suppressive effect of psychological stress on varicella-zoster cell-mediated immunity.

D. Background

Herpes zoster, also known as shingles, is a frequent neurocutaneous infection caused by reactivation of VZV, which lies latent in the sensory ganglia after the primary infection chickenpox.¹ Reactivation occurs when the cell-mediated immunity towards VZV wanes below a certain critical level.¹ Accordingly, the risk of herpes zoster is increased among elderly because of immunosenescence, among patients with inherited cell-mediated immunodeficiency, and among patients with immunosuppression acquired by drugs (*e.g.* patients receiving corticosteroids or chemotherapy), radiotherapy, or the disease (*e.g.* HIV or haematological cancer).^{1,2}

Psychological stress is associated with activation of the hypothalamic-pituitary-adrenal axis and thereby suppression of the immune system.^{3,4} It is therefore possible that psychological stress increases the risk of herpes zoster. For example, it has been demonstrated that VZV-specific cell-mediated immunity is reduced in patients with major depression⁵ and that it correlates negatively with the severity of depressive symptoms.⁶ Furthermore, the immunological response to the zoster vaccine is reduced in patients with untreated depression compared with individuals treated with antidepressants and individuals without depression.⁷ However, data from large epidemiological studies on the association between psychological stressors and risk of herpes zoster are sparse and conflicting.

Previous epidemiological studies on psychiatric disease and risk of herpes zoster have considered primarily depression without examining the association by timing and severity.^{2,8-15} Studies on negative life events, such as partner bereavement, are also sparse¹⁵⁻¹⁹ and interpretation is hampered by study limitations, such as potential selection bias (non-response and volunteer bias),^{15,17-19} lack of interviewer blinding,^{15,17} and small study size.^{15,17-19} Furthermore, various exposure windows and definitions have been employed¹⁵⁻¹⁹ and only one study performed detailed analyses according to time passed between the life event and diagnosis of herpes zoster.¹⁶

E. Study Type

The study is hypothesis testing. The null hypothesis is that psychological stress is not associated with an increased risk of being diagnosed with herpes zoster.

F. Study Design

We propose to conduct a matched case-control study using data from CPRD linked to HES. This design is efficient for examining the wide range of psychological stressors considered in this study.

G. Sample Size

Table 1 provides power calculations for selected psychological stressors, assuming a case: control ratio of 4, an alpha-level of 0.05, and inclusion of 144,000 incident cases of herpes zoster.² Stata 14 was used for all calculations.

Table 1. Power calculation for the proposed study

Exposure	Prevalence	Power to detect an OR of 1.1	Power to detect an OR of 1.2	Power to detect an OR of 1.3
Any depression diagnosis	4% ²	100%	100%	100%
Referral to psychiatrist, any	5.1% ²⁰	100%	100%	100%
Referral to psychologist/psychiatrist, past year	1.1% ²⁰	93%	100%	100%
Spousal bereavement past 30 days	0.4% ²¹	56%	98%	100%

H. Data Linkage Required (if applicable)

The CPRD data will be linked to inpatient HES data to obtain data on diagnoses of herpes zoster, exposures and covariates in the hospital-based setting. Identification of diagnoses in the hospital-based setting is important for completeness of variables and thus the study validity. Furthermore, we will obtain data on socioeconomic status (for the area of residence through linkage to the Index of Multiple Deprivation, version 2010). The HES data will be included in the main analysis to increase completeness of diagnoses and the accuracy of timing, although only 60% of patients from the CPRD have data available in the HES database. Socioeconomic status as measured by the Index of Multiple Deprivation will be included in the multivariable models in a sensitivity analysis restricting to patients without missing data on this variable (approximately 60%).

I. Study Population

We will use CPRD and HES to identify all patients with a record of herpes zoster between 1 January 2000 and 31 December 2014 (or 31 March 2014 if a more up to date version of HES does not become available during the study) and at least 12 months of follow-up before diagnosis. We will restrict to patients aged 18 years or older because of differences in the epidemiology of herpes zoster in children and adults. For inclusion of cases with hospital diagnosis of herpes zoster, we will only consider those with a first-listed (primary) diagnosis of herpes zoster. The date of diagnosis in the CPRD or admission in HES will be considered the index date. In case of diagnosis in both CPRD and HES, we will consider the earliest diagnosis. We will only consider patients with no previous codes for herpes zoster or postherpetic neuralgia in the CPRD or HES (Read codes or ICD-10 codes in any position). Thus, if the earliest mention of herpes zoster in the data is a secondary code in HES, we will exclude the patient from the study. We expect to identify approximately 144,000 incident cases of herpes zoster.² We will define herpes zoster according to a code list used in a previously published study on risk factors for herpes zoster conducted by our research group (Supplementary Appendix).² The list will be updated slightly to include new codes.

J. Selection of comparison group(s) or controls

We will use incidence density sampling to randomly select up to four controls per case matched by practice, sex and age (within 1 year). Controls have to be registered in the practice at the index date

of the case and for at least 12 months before and should have no history of herpes zoster or post-herpetic neuralgia. Matching by practice controls for practice-level socioeconomic status. Controls will be assigned an index date identical to that of their case. We will exclude inactive controls, defined as individuals with no contact with their practice (*i.e.* no consultation records of any kind, including repeat prescriptions, face to face consultations, and telephone consultations) from six months before to 12 months after the index date.

K. Exposures, Outcomes and Covariates

Definitions of exposures and covariates are described in the following. The definition of the outcome, herpes zoster, is described in section I. Preliminary code lists for exposures are provided in the Supplementary Appendix. When necessary, we will differentiate between codes of psychiatric disease that indicate definite, possible (e.g. “depression interim review”) or non-specific/other diagnoses. Code lists for covariates will be based on modified versions of lists in Caliber²² and the previous study on herpes zoster risk factors.²

Partner bereavement

We will define partner bereavement as the death of a cohabitee prior to the index date, as previously described by Shah *et al.*²³ Cohabitees will be identified through CPRD using the family practice number, which identifies people who are living in the same household or otherwise are associated (*e.g.* live in the same institution). To avoid including the death of children in families, we will restrict to couples of the opposite sex, with an age gap of 10 years or less and with no younger adult in the household within 15 years of either of the couple.²³ Also, we will exclude couples where 1) a patient has codes in the primary care record that indicate residence in a communal establishment before the index date and/or 2) both individuals in the couple are 95 years of age or older. Through comparison with contemporary national representative household surveys in England, it has been shown that among persons aged ≥ 60 years, couples of the opposite sex with an age difference of less than 10 years who live together, 99.4% identify themselves as married or cohabitating.²³ Because the validity of our algorithm is expected to be lower for younger persons, we will restrict the study population to persons aged 40 years or older. Also, we will stratify the results by age.

We will use the CPRD death date in the deceased partner’s primary care record as the date of bereavement. In analyses, we will consider any prior bereavement as well as differentiate between whether partner bereavement occurred within 0–7 days, 8–14 days, 15–30 days, 31–90 days, 91–365 days, 366–1095 days or >1095 days before the index date. The reference group for the analyses will be persons who have not previously experienced partner death.

We will aim to explore whether the association between bereavement and herpes zoster depends on whether the death of partner was unforeseen. We will ascertain the primary care (CPRD) and hospital record (HES) for deceased partners at one month before their date of death and compute their age-adjusted Charlson Comorbidity Index (ACCI), which is widely used to predict mortality.²⁴ The original Charlson Comorbidity Index assigns 0 to 6 points to a range of chronic diseases according to their ability to predict death.²⁴ In the age-adjusted index, additional points are given according to age (1 point: 50–59 years; 2 point: 60–69 years; 3 points: 70–79 years; 4 points: 80–89 years; 5 points: 90–99 years).²⁴ Based on the total ACCI score, we will the group study participants

into three categories of risk of partner death: lowest risk (0–5 points), intermediate risk (6–8 points), or highest risk (9–16 points). The CCI has previously been used to estimate risk of death in studies of bereavement.^{21,25} As the ACCI includes a wide range of diseases, which may not all help partners to predict the expectedness of death, we will perform analyses according to whether partners had a previous healthcare record of terminal disease (as indicated by *e.g.* stay at hospice or metastatic cancer).

Diagnoses or symptoms of psychiatric disease or stress

Using CPRD and HES data, we will identify any history of depressive disorder, anxiety disorder (phobic anxiety disorders and other anxiety disorders) or acute stress and adjustment disorder in the electronic medical record prior to the index date. Since 2004, there has been an increasing use of symptoms rather than diagnosis codes for depression in CPRD.²⁶ Thus, to increase the completeness of our codes lists, we will include both Read codes for diagnoses and symptoms of depression and anxiety disorders.

The reference group for all analyses will be persons with no record of any of the psychiatric diseases or symptoms prior to index date. We will examine the association by timing and severity of these diseases. Based on the most recent record of psychological stress prior to index date, we will define timing as current (≤ 90 days before index date), recent (>90 days to 365 days before index date), former (>365 days before index date), and no (no previous record) psychological distress. Furthermore, we will subdivide the current group into newly diagnosed (first-ever record 90 days or less before the index date) and chronic (others). We will categorise severity as severe (requiring inpatient admission for >1 day), moderate (requiring referral from general practice to other mental health service) or mild (remaining patients) based on healthcare records within 90 days before index date. For the definition of severe disease, we will only consider those admitted with one of the psychiatric diseases (depressive disorder, anxiety disorder, or acute stress and adjustment disorder) as primary diagnosis for more than one day.

Covariates

From CPRD and HES, we will retrieve data on potential risk factors prior to index date index date (as defined in the study by Forbes *et al.*)²: Rheumatoid arthritis; systemic lupus erythematosus; inflammatory bowel disease; chronic obstructive pulmonary disease; asthma; chronic kidney disease (including those with kidney transplant or kidney dialysis); diabetes (type I, type II, or missing); human immunodeficiency virus infection, haematopoietic stem cell transplantation, myeloma, or “other unspecified cellular immune deficiencies” (for example, pancytopenia); recent history (less than two years before index date) of leukaemia, lymphoma, or bone marrow transplant; use of oral corticosteroids, other immunosuppressive treatments or use of inhaled corticosteroids within prior three months; smoking status (current smoker, ex-smoker, non-smoker); alcohol consumption (current drinker, ex-drinker, non-drinker); and body mass index (underweight (<18.5 kg/m²), normal weight (18.5–24.9 kg/m²), overweight (25–29.9 kg/m²), obese (≥ 30 kg/m²)). Read codes for BMI category will not be used, because they are rarely recorded. The categorisation of lifestyle variables will be pragmatically based on status recorded closest to the index date, with records within -1 year to +1 month from index date regarded as the best, +1 months to +1 years

from index date being second best, the nearest before -1 year from index date as the third best, and within +1 year from index date being least best.²

L. Data/ Statistical analysis

We will keep the analysis of bereavement and the psychiatric diseases separate, as we intend to publish them separately (see section Q).

We will characterise the population by case-control status and exposures. We will use conditional logistic regression to compute unadjusted odds ratios, associating the various measures of psychological stress with herpes zoster. We will consider the psychiatric diseases both together and separately. Definitions and reference groups described in section K will be applied. We will use 99% confidence intervals to account for the multiple measures included and to reduce the chance of detecting clinically insignificant associations. Please see amendment regarding choice of precision by the end of the protocol.

Given the density case-control study design, the odds ratios provide an unbiased estimate of the incidence rate ratios.²⁷ To account for potential confounding, we will fit two multivariable conditional logistic regression models. The first model will include all the aforementioned pre-specified covariates except for lifestyle factors and the second model will additionally account for lifestyle factors. The second model will include only those with complete data for all variables (estimated 90% of cases and controls).² We will control for age, sex and practice-level socioeconomic status by conditioning on matching factors.

We will examine for presence of effect measure modification by stratifying the results for current psychological stress by categories of age (<50, 50–59, 60–69, and ≥70 years) and sex. For bereavement, we will use both a 30-day and 90-day exposure window in the stratified analyses. To examine whether any association between bereavement and herpes zoster is mediated through depression or anxiety, we will also stratify the results by recent diagnoses of these conditions.

To quantify the effects of the psychological stress factors in absolute terms, we will compute the age-specific rate of zoster for each factor by multiplying the age-specific effect estimates by the age-specific rate of zoster in the general population in 2010 (estimated from CPRD).

We will perform a number of sensitivity analyses to address potential limitations of our data:

1. We will repeat analyses for the association between bereavement and herpes zoster after restricting to persons with evidence of having a partner, to examine whether using only persons who have a partner in the reference group affects the results.
2. We will test the completeness of our bereavement algorithm by examining how many of the bereaved subjects are identified by using CPRD codes for partner bereavement. Bereavement codes will however not be used in the main analysis, because they may be coded differentially (depending on consulting behaviour) and because timing of partner death is assumed to be less accurate than that derived from our algorithm.
3. We will examine the impact of using various cut-offs between current and recent (7, 14, 15, 30, and 180 days) psychiatric stress instead of 90 days.
4. We will perform analyses separating definite (with and without symptoms included), possible and unspecific/other diagnoses of psychiatric disease.

5. Under the assumption that patients who receive pharmacological therapy are more likely to have severe depression, we will change the severity definition to include the following categories: very severe (requiring inpatient admission for >1 day), severe (written prescription for an antidepressant recorded within 2 weeks to 90 days prior to index date), moderate (requiring referral from general practice to other mental health service) or mild (remaining patients) based on healthcare records within 2 weeks to 90 days before index date. The 2-weekiSimilarly, we will perform analyses after excluding those with previous antidepressant prescription from the reference group for psychiatric diseases.
6. We will repeat analyses examining each association for persons with a record of that psychological stressor only (e.g. ‘depression only’), as some persons may have overlapping conditions.
7. We will perform the analysis after multiple imputation of missing information on lifestyle factors using chained equations,²⁸ as described by Forbes *et al.*²
8. We will additionally adjust for Index of Multiple Deprivation score (categorised in quintiles) among the approximately 60% who have agreed their electronic medical records linked to other dataset.

All analyses will be performed using STATA statistical software package.

M. Plan for addressing confounding

We will use multivariable conditional regression to adjust for risk factors listed in section K and (through conditioning) for matching factors (age, sex and practice). These covariables were selected based on the literature.

N. Plan for addressing missing data

Please see section L.

O. Limitations of the study design, data sources and analytical methods

There are some potential limitations to the proposed study, which we discuss in the following.

Partner bereavement and psychiatric diseases may affect disease perception and health-seeking behaviour, and thus the chance of having herpes zoster diagnosed. For example, depressive patients may have a stronger perception of mild skin symptoms.²⁹ On the other hand, patients experiencing psychological stress may not have energy to seek treatment for minor health problems. It is therefore difficult to predict in which direction such bias would affect our results. We will partly account for health-seeking behaviour by including data on participants’ socioeconomic status. Also, due to the painful symptoms, we believe that individuals with herpes zoster would present to their general practitioner.^{30,31}

Some misclassification of partner bereavement is possible, as our definition of partners requires that couples are registered with the same general practice and have an age difference of 10 years or less. Also, the nature of the relationship may be misclassified, as some ‘partners’ may be otherwise

associated (*e.g.* friends). Finally, we could miss some partners if the family practice identifier is used inconsistently in some practices or if the partner of a case or control uses a different general practitioner, who does not report in the CPRD. However, we do not believe that this misclassification is differential. Thus, if we find an association between bereavement and herpes zoster, it cannot be explained by such misclassification. Also, the sensitivity analysis restricting to partners only would limit such bias.

Expectation of death is difficult to categorise using data from electronic medical records and the psychological distress associated with expected death from a spouse may vary depending on the type of chronic disease. As we rely completely on the age-adjusted Charlson Comorbidity Index and utilisation of health services, the effect of probability of death may represent a mixed group of patients. This mix could possibly attenuate any true difference between groups of expected and unexpected partner death. We will explore the effect of expected death in various sensitivity analyses, which may point to limitations in our main definition.

We may underestimate use of prescription medications, because the electronic records do not include prescriptions written by hospital physicians. However, prescription treatment initiated by specialists is typically repeated by the general practitioner, so this likely affects mainly first-time prescriptions. Also, written prescriptions do not necessarily correspond to use. Nonetheless, we believe this is a minor issue, as we are interested in using prescriptions as a proxy measure of underlying psychological stress rather than the effect of the drug in itself.

Although we will adjust for various comorbidities and lifestyle factors, we may have residual confounding as partners typically share health characteristics and psychological stress may be associated with unhealthy lifestyle.

Misclassification of herpes zoster is possible, as it is usually a clinical diagnosis. However, because other validation studies report a high positive predictive value of physician-diagnosed herpes zoster,³²⁻³⁶ we believe that the impact of misclassification on our results will be small.

Finally, we will not include outpatient HES data and inpatient HES data and the Index of Multiple Deprivation scores are only available for approximately 60% of the study population. Because herpes zoster is treated primarily in general practice, this lack of data will have only minor effect on the study population sample. However, it may result in misclassification of exposure and residual confounding. The sensitivity analysis restricting to the study subjects with HES inpatient data and the Index of Multiple Deprivation scores may aid in uncovering such bias.

P. Patient or user group involvement (if applicable)

Patients have not been involved in the planning of the study to date. We aim to disseminate any important findings to the public and appropriate patient groups as part of the publication process.

Q. Plans for disseminating and communicating study results, including the presence or absence of any restrictions on the extent and timing of publication

We intend to publish our findings in a peer-reviewed journal and to present them at relevant scientific conferences. Parallel analyses will be conducted on nationwide Danish registry data. All

approvals have been obtained for conducting the Danish study. We aim to publish the results from UK and Denmark together in two papers on partner bereavement and psychiatric disease (remaining exposures) respectively. This distinction will be made because partner bereavement is considered a natural response to a life event, whereas the psychiatric diseases (e.g. depression) are considered pathological reactions. Necessary approvals for use of the Danish data have already been obtained.

Amendments

- Originally, we stated that we used 99% confidence intervals "to account for the multiple measures included and to reduce the chance of detecting clinically insignificant associations" (L. Data/ Statistical analysis). However, we want to specify that in reality we consider the choice of precision arbitrary. We will base our interpretations on clinical significance of the point estimates rather than dichotomising to statistical significance according to an arbitrary significance level.³⁷
- Final code lists used are attached as an appendix.

BNF codes for antidepressant drugs (for sensitivity analysis)

BNF section 4.3.2 Monoamine oxidase inhibitors

BNF section 4.3.4. Other antidepressants

BNF section 4.3.3. Serotonin re-uptake inhibitors (SSRIs) antidepressants

BNF section 4.3.1. Tricyclic antidepressants (TCAs)

*We will not include psychiatric disorders limited to childhood. Organic depression/anxiety will be included in the "non-specific/other" group, they are not classified with depression according to the ICD-10. Similarly, codes which are unspecific with regard to timing (codes indicating e.g. remission) will be categorised as non-specific/other. Furthermore, "non-specific/other depression" includes also codes for schizoaffective disorder with depression, post-schizophrenic depression, drug-induced depression, depression in association with pregnancy, and dysthymia.
