SUPPLEMENTARY DATA

Sugar concentration quantification

NMR Analyses: The extraction of the metabolites was done in 50 mg of freeze-lyophilized plum fruit and leaf tissues using methanol:chloroform:water (2:2:1) followed by sonication for 1h. After centrifugation at 10,500 xg for 20 min at 4°C, the upper hydroalcoholic phase was carefully separated and dried under Speed-Vac for 24h. To evaluate the reproducibility of sample preparation, three portions of each sample were used to perform three extractions. For the ¹H-NMR quantification, the dry residue of the hydroalcoholic phase was dissolved in 0.75 mL of deuterium oxide phosphate buffer (150 mM, pH 7.0) measured by a glass BNC electrode (Sigma-Aldrich) containing 3 mM 4,4- Trimethyl-4-silyl propanoic acid (TSP) as an internal standard. All ¹H-NMR spectra were recorded at 298 °K on a Bruker AVIII HD 500 NMR spectrometer (500.13 MHz for ¹H) equipped with a 5 mm CPP BBO cryogenic probe (Bruker Biospin, Germany). ¹H spectra were referenced to TSP signal ($\delta = 0.00$ ppm), whereas ¹³C spectra were referenced to CH-¹ resonance of α-D-glucose ($\delta = 93.10$ ppm). A standard one-dimensional pulse sequence noesypr1d (recycle delay-90°-t1-90°-tm-90°-acquisition) was used to obtain metabolic profiles of plum fruit and leaf extracts with the 90° pulse length of about 11 μ s and t1 of 3 μ s. Water suppression was achieved with a weak irradiation during the recycle delay (RD = 2 s) and mixing time (100 ms). Sixty-four transients were collected into 32,768 data points for each spectrum with a spectral width of 8 kHz. An exponential window function with line-broadening factor of 0.5 Hz was applied to free induction decays prior to Fourier transformation (FT). For resonance assignment purposes, ¹H-¹H-correlation spectroscopy (COSY; cosygpqfpr), ¹H-¹H-total correlation spectroscopy (TOCSY; mlevphpr) and ¹H-¹³C-heteronuclear single quantum coherence (HSQC; hsqcetgp) two-dimensional NMR spectra was acquired for selected samples. In COSY and TOCSY experiments, 48 transients were collected

into 2,048 data points for each 256 increments with the spectral width of 12 ppm for both dimensions. Phase insensitive mode was used with gradient selection for the COSY experiments whereas the well-known MLEV-17 was employed as the spin-lock scheme in the phase sensitive. The TOCSY experiment (time-proportional phase incrementation) had a mixing time of 100 ms. ^1H - ^{13}C HSQC NMR spectra were recorded using the gradient selected sequences with 200 transients and 2,048 data points for each of the 1,064 increments. The spectral widths were 6,313 Hz for ^1H and 26,410 Hz for ^{13}C for HSQC experiments. The data were Fourier transformed into a 4 x 2k matrix with appropriate apodization functions. ^1H NMR spectra were manually corrected for phase and baseline distortions using TOPSPIN version 3.2 (Bruker Biospin) and the spectral region of δ =0.5 to 9.5 was uniformly integrated into 3,166 buckets with width of 0.003 ppm (1.8 Hz) using the Chenomx software version 3.8.3 (Bruker Biospin). The region δ =4.67 to 5.15 was discarded to eliminate the effects of imperfect water presaturation. The spectral areas of all buckets were normalized to the weight of extracts employed for measurements. The intensities of 60 selected ^1H resonances due hydro-alcoholic metabolites were measured with respect to the intensity of TSP signal used as internal standard with a concentration of 3 mM.

UHPLC-QTOF-MS/MS analyses: The chemical extraction was done in 50 mg of plum fruit and leaf lyophilized tissues using chloroform:methanol:water (1:2:2) followed by sonication of 1h. Samples were centrifuged at 18,000 xg during 5 min at 4°C. The supernatant was filtered through a 0.2 μm Whatman syringe filter and these extracts were used for the UHPLC-QTOF-MS/MS analysis. Separation of sugars from plum extracts (fruits and leaves) was performed on a Waters Acquity iClass UHPLC (Waters Corporation, Milford, MA) consisting of a vacuum degasser, an auto-sampler and a binary pump. This instrument was equipped with a BEH Amide UHPLC column (2.1 x 100 mm, 1.7 μm) from Waters Corporation. Acidified water (0.1% formic acid, v/v) and Acetonitrile were used as mobile phases A and B, respectively. The gradient was programmed as follows: 0 min, 99% B; 7 min, 30% B; 7.1 min, 99% B; 10 min, 99% B; and finally, the initial conditions were held for 7 min as a re-equilibration step. The flow rate was set at 0.30 mL/min throughout the gradient. The injection volume was 5 μL and the column temperature was maintained at 40 °C. The UHPLC system was coupled to a quadrupole-time-of-flight (maXis Impact HR Q-TOF-MS, Bruker Daltonik GmbH, Bremen, Germany) orthogonal accelerated Q-TOF mass spectrometer, equipped with an electrospray ionization source (ESI).

Parameters for analysis were set using negative and positive ion modes, with spectra acquired over a mass range from 50 to 1200 m/z. The optimum values of the ESI-MS parameters were: capillary voltage, -4.0 and +4.5 kV; drying gas temperature, 200 °C; drying gas flow, 8.0 L/ min; nebulizing gas pressure, 2 bars; collision RF, 150 Vpp; transfer time 72 µs, and pre-pulse storage, 5 µs. The MS data were processed through Data Analysis 4.0 software (Bruker Daltonics, Bremen, Germany) which provided a list of possible elemental formulas by using the Generate Molecular Formula™ editor. The editor uses a CHNO algorithm, which provides standard functionalities, such as maximum/minimum elemental range, and a sophisticated comparison of the theoretical with the measured isotope pattern (mSigma value), for increasing the confidence in the suggested molecular formula. The widely-accepted accuracy for confirmation of elemental compositions has been established as 5 ppm. At some stage in the UHPLC method development, an external apparatus calibration was performed using a KD Scientific syringe pump (Vernon Hills, IL) directly linked to the interface, passing a solution of sodium formate with a flow rate of 180 µL/h. Using this method, an exact calibration curve based on numerous cluster masses each differing by 68 Da (CHO_2Na) was obtained. Due to the compensation of temperature drift in the Q-TOF, this external calibration provided accurate mass values for a complete run without the need for a dual sprayer set up for internal mass calibration.

Table S1. List of primers used in qRT-PCR.

Table S2. A list of the sugar metabolism-associated genes from RNA-Seq analyses and their corresponding number of edges. Sugar metabolism-associated genes, obtained from the differentially expressed genes (DEGs) from RNA-Seq analysis (by GO terms and literature data), organized by module names as indicated in Fig. 4 are shown. Genes in bold type correspond to the 28 sugar metabolism-related genes significantly correlated with sugar contents through PCC analysis (Table 2). Number of edges were estimated using as a cutoff a Weighted Gene Co-expression Network Analysis (WGCNA) edge weight ≥ 0.5 , as indicated in “Materials and Methods”.

Fig. S3. Relative gene expression levels of Sucrose metabolism-associated pathways. Relative gene expression levels of sucrose metabolism-associated pathways in (A) fruits and (B) leaves of Santa Rosa (SR; black bars) and Sweet Miriam (SM; white bars) throughout development (S2 (pit hardening)) and ripening (S3/S4 (mature), S4-I (commercial harvest), S4-II (fully-ripe)) stages on the tree. Values were calculated and normalized using the SAND protein-related trafficking protein (*MON*) as reference gene and are presented as means \pm SE (n=6). The data were analyzed using two-way ANOVA followed by Tukey's test. Different letters indicate significant differences ($p<0.05$). Sucrose phosphate synthase (*SPS*); Sucrose synthase (*SuSy*); cell wall invertase (*CWINV*); vacuolar invertase (*VINV*); cytosolic invertase (*CytINV*); Invertase inhibitor (*INVINH*).

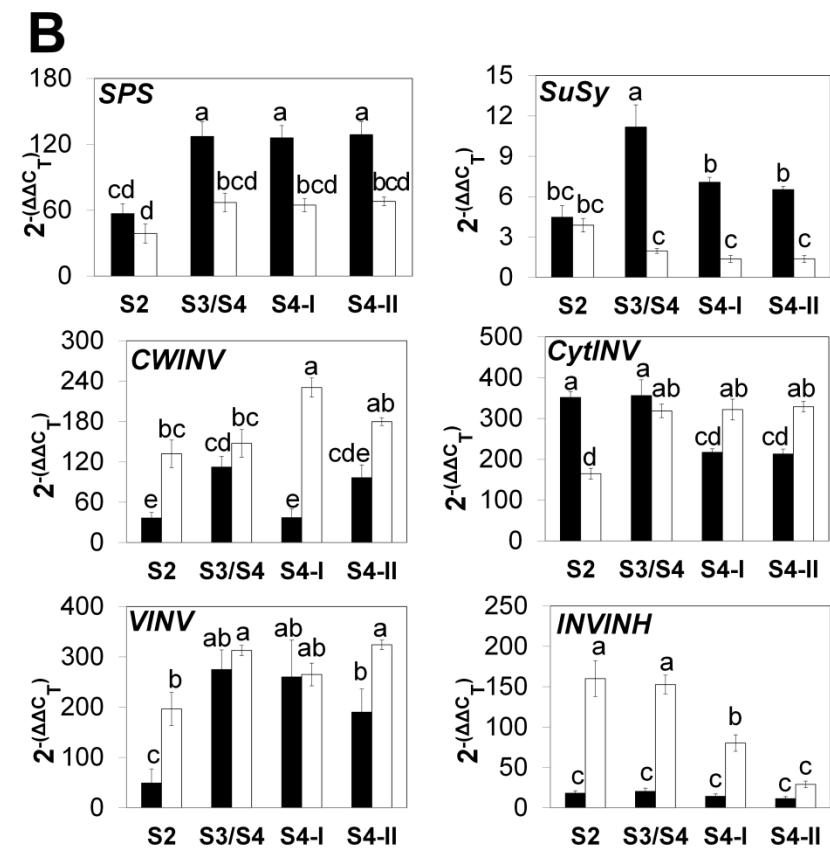

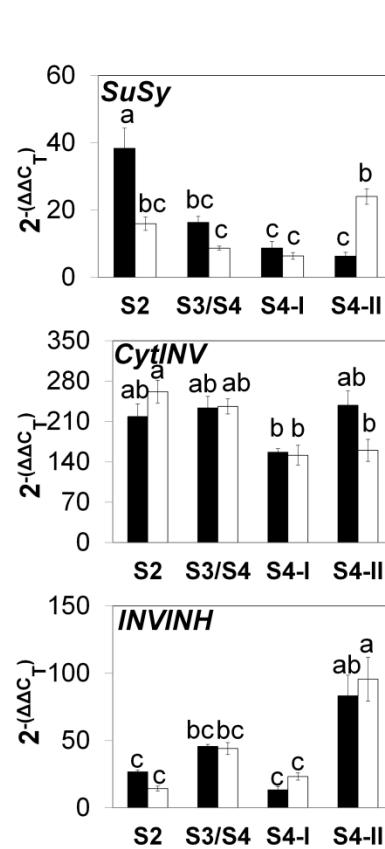

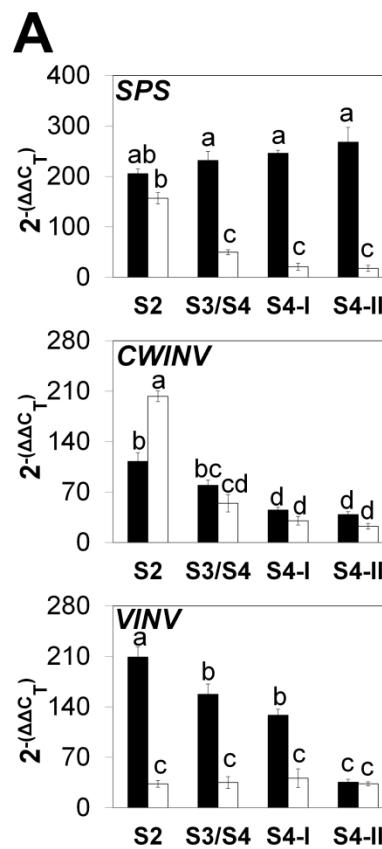

Fig. S4. Relative gene expression levels of Sorbitol metabolism-associated pathways. Relative gene expression levels of sorbitol metabolism-associated pathways in (A) fruits and (B) leaves of Santa Rosa (SR; black bars) and Sweet Miriam (SM; white bars) throughout development (S2 (pit hardening)) and ripening (S3/S4 (mature), S4-I (commercial harvest), S4-II (fully-ripe)) stages on the tree. Values were calculated and normalized using the SAND protein-related trafficking protein (*MON*) as reference gene and are presented as means \pm SE (n=6). The data were analyzed using two-way ANOVA followed by Tukey's test. Different letters indicate significant differences (p<0.05). Sorbitol-6-phosphate dehydrogenase (*S6PDH*); NAD⁺-dependent sorbitol dehydrogenase (*NAD⁺-SDH*); hexokinase (*HK*).

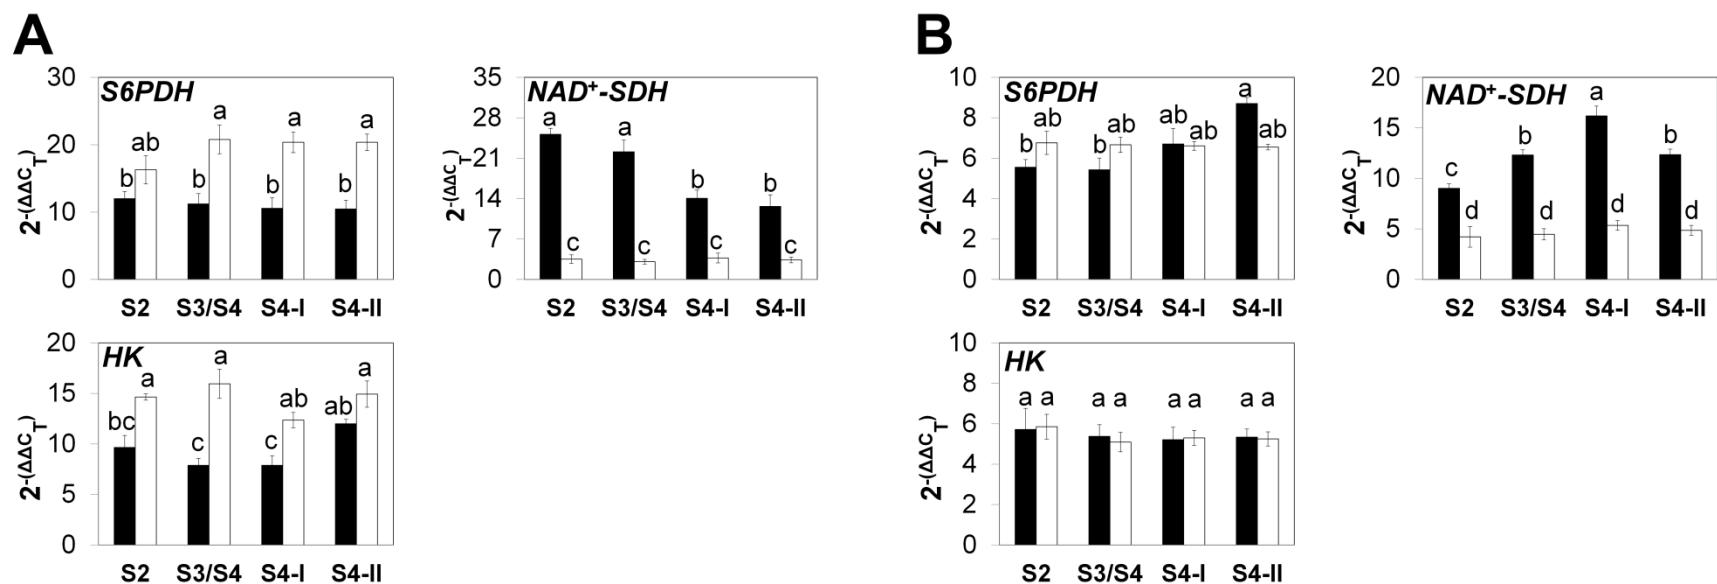

Fig. S5. Relative gene expression levels of minor sugar metabolism-associated pathways. Relative gene expression levels of galactose, galactinol, raffinose and trehalose metabolism-associated pathways in (A) fruits and (B) leaves of Santa Rosa (SR; black bars) and Sweet Miriam (SM; white bars) throughout development (S2 (pit hardening)) and ripening (S3/S4 (mature), S4-I (commercial harvest), S4-II (fully-ripe)) stages on the tree. Values were calculated and normalized using the SAND protein-related trafficking protein (*MOM*) as reference gene and are presented as means \pm SE (n=6). The data were analyzed using two-way ANOVA followed by Tukey's test. Different letters indicate significant differences (p<0.05). Alpha-Galactosidase (α -GAL); Beta-Galactosidase (β -GAL); Galatokinase (GALK); Galactinol synthase (GoIS); Raffinose synthase (RS); Trehalase (TRE).
