

BMJ Open

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email info.bmjopen@bmj.com

CKD self-management interventions

ABSTRACT

Objective: To systematically identify and describe self-management interventions for adult patients with CKD.

Setting: Community-based

Participants: Adults with CKD Stages 1 – 5 (not requiring kidney replacement therapy).

Interventions: Self-management strategies for adults with CKD.

Primary and secondary outcome measures: Using a scoping review, electronic databases and grey literature were searched to October 2016 to identify self-management interventions for adults with CKD Stages 1 – 5 (not requiring kidney replacement therapy). Randomized controlled trials (RCTs), non-RCTs, qualitative and mixed method studies were included and study selection and data extraction were independently performed by two reviewers. Outcomes included behaviors, cognitions, physiological measures, symptoms, health status and health care.

Results: 50 studies (19 RCTs, 7 quasi-experimental, 5 observational, 13 pre-post intervention, 1 mixed methods and 5 qualitative) reporting 45 interventions were included. The most common intervention topic was diet/nutrition and interventions were regularly delivered face to face. Interventions were administered by a variety of providers, with nursing professionals the most common health professional group. Cognitions (i.e. changes in general CKD knowledge, perceived self-management, and motivation) was the most frequently reported outcome domain that showed improvement. Less than 1% of the interventions were co-developed with patients and 20% were based on a theory or framework.

1
2
3 **Conclusions:** There was a wide range of self-management interventions with considerable

variability in outcomes for adults with CKD. Major gaps in the literature include lack of patient engagement in the design of the interventions, with the majority of interventions not applying a behavioral change theory to inform their development. This work highlights the need to involve patients to co-develop and evaluate a self-management intervention based on sound theories and clinical evidence.

Key words: Chronic kidney disease, scoping review, self-management, patient centred-care

Strengths and limitations of this study:

- A strength of this study is that it is the first scoping review to apply the principles of patient-oriented research, where patient partners were engaged in determining the research question, advising us on search terms and reviewing the results to ensure we captured and reported the data meaningfully.
- This scoping review is comprehensive in nature, inclusion of all study designs and consideration of self-management features that have not been investigated previously.
- Due to the heterogeneous nature of the literature, it was challenging to synthesize the data. To address this challenge the two reviewers used two standardized tools to independently extract data, and independently coded the outcomes into categories using the Self-and Family Management Framework.
- A limitation of this scoping review is that we were unable to assess the self-management outcomes in terms of sustained changes in behavior, physiological, and health status.

CKD self-management interventions

- The scoping review was unable to draw conclusions regarding the most effective self-management intervention for adult patients with CKD, keeping in mind our aim was to review the breadth of the current literature and present the gaps that exist.

For peer review only

INTRODUCTION

Chronic kidney disease (CKD) is associated with adverse health outcomes, poor quality of life and high health care costs (1). Patients with CKD often experience a number of comorbidities including diabetes, cardiovascular disease and depression (2). They must balance the medical management of their kidney disease and other chronic conditions with demands of their daily lives, including managing the emotional and psychosocial consequences of living with chronic disease. In a recent national research priority setting process, individuals with non-dialysis CKD, their caregivers, and clinicians and policy makers involved in their care, identified the need to develop optimal strategies to enable patients to manage their CKD and related comorbidities to slow or prevent the progression to end-stage kidney disease (ESKD) (3). International data in research priority setting for kidney disease also highlights self-management as a top priority to prevent progression (4).

Self-management interventions aim to facilitate an individual's ability to make lifestyle changes and manage symptoms, treatment, and the physical and psychosocial consequences inherent in living with CKD and associated comorbidities (5). Self-management of CKD involves focusing on illness needs (developing knowledge, skills and confidence to manage medical aspects), activating resources (identifying and accessing resources and supports) and living with the condition (learning to cope with the condition and its impact on their lives as well as the emotional consequences of the illness) (6). Self-management requires patient engagement, however, the degree to which patients are able or willing to participate in self-management can vary, and individual and health system factors may serve as facilitators or barriers to self-management processes (7).

CKD self-management interventions

1
2
3 Despite the high prevalence of CKD and its impact on patient outcomes, there is limited
4
5 evidence on the effectiveness of self-management interventions. A prior systematic review (8)
6
7 and three integrative reviews (9-11) found that self-management interventions were variable in
8
9 their effectiveness for managing and preventing progression of CKD. While these reviews add to
10
11 the knowledge base, there has been limited information on describing complex self-management
12
13 interventions in detail and providing structured accounts of the interventions and outcomes. In
14
15 particular, features of self-management interventions such as patient centeredness, applicability
16
17 to co-morbidities associated with CKD, physiological and non-physiological outcomes, and
18
19 application of any behavioral change theories are often lacking. Self-management interventions
20
21 need to be tailored to suit diverse patient needs and preferences, as well as the local health care
22
23 context (7). Therefore, investigating the “who”, “what” and the “how” of self-management
24
25 interventions is crucial.
26
27
28
29

30
31 To our knowledge there is no literature synthesis that systematically and comprehensively
32
33 summarizes the breadth of evidence found in primary quantitative, qualitative and mixed
34
35 methods research regarding self-management interventions for adult patients with CKD. Using a
36
37 scoping review methodology helps us to understand the range and types of interventions
38
39 including both educational and support interventions for CKD to inform the future design of a
40
41 self-management intervention. Therefore, we conducted a scoping review to identify and
42
43 describe self-management interventions for adult patients with CKD (stages 1 – 5; non-dialysis,
44
45 non-transplant).

MATERIALS AND METHODS

We used a scoping review methodology to enable us to incorporate a broad range of studies and to summarize the knowledge from a variety of sources and types of evidence (12). Our aim was to identify the gaps within the literature for self-management interventions and inform future primary research in this area. A unique and important aspect was the involvement of “patient partners”. Through a national initiative, Canadians Seeking Solutions and Innovations to Overcome CKD (Can-SOLVE CKD), patients work side by side with researchers, clinicians and decision makers to address patient-oriented research priorities (13). Our research team includes Can-SOLVE CKD patient partners with CKD and caregivers (13). Using the Joanna Briggs Institute framework for scoping reviews we undertook the following steps: (1) identified the research question, (2) identified relevant studies, (3) completed study selection, (4) charted, collated, summarized and reported the results, and (5) consulted with our patient partners (12, 14). These steps were iterative to ensure comprehensive inclusion of the literature and continued meaningful engagement with our patient partners. This study does not involve human participants and is exempt from ethics approval.

Research aim

Our scoping review aimed to determine the available self-management interventions for adults aged 18 years and over and diagnosed with CKD Stages 1 – 5 (not requiring dialysis or transplant).

Search and selection of studies

We worked with an information specialist (DL) to identify key words that represented the population (CKD) and the intervention (self-management). We searched a broad range of

CKD self-management interventions

1
2
3 information sources including the following online databases: MEDLINE (OVID), EMBASE,
4
5 PsycINFO, Cochrane Central Register of Controlled Trials, CINAHL Plus and Cochrane
6
7 Database of Systematic Reviews for published studies, with no limits on date (inception to
8
9 October 2016), language, age or study design. We also searched Web of Science from 2006 –
10
11 October 2016 to capture recently published meeting abstracts and summaries. Using the
12
13 Canadian Agency for Drugs and Technology (CADTH) Grey Matters approach, a “search tool
14
15 for evidence-based searching on the Internet” (15) we searched Google Canada, Health
16
17 Technology Assessment (HTA) agencies (Canada, Australia, Ireland, UK and US), and Clinical
18
19 Trials databases (Biomed Central – ISRCTN Registry, US National Institutes of Health,
20
21 ClinicalTrials.gov) during October 2016 with no language restrictions (Table S1). Our search
22
23 strategy for grey literature was guided by the specific database (i.e. Google search operators,
24
25 website search filters) and was completed within a single session for each search strategy to
26
27 ensure consistency due to the dynamic nature of the Internet (Table S2). Two reviewers (BK and
28
29 MD) also reviewed the reference lists of included studies, along with those identified in past
30
31 systematic and integrative reviews of our research topic. We contacted authors of relevant
32
33 protocols and conference abstracts to ascertain if their work and findings were published.
34
35
36
37
38
39

40
41 A study was included if the population involved adults with CKD (stages 1 – 5, non-dialysis,
42
43 non-transplant). Self-management interventions included strategies, tools, or resources in any
44
45 delivery format (print, electronic, face to face, etc.) that facilitated an individual’s ability to make
46
47 lifestyle changes or to manage symptoms, treatment, or the physical and psychosocial
48
49 consequences inherent in living with CKD and other associated comorbidities. Interventions
50
51 targeted only at selection of treatment for ESKD (i.e. dialysis, kidney transplant) were excluded.
52
53
54 Other self-management interventions or standard care were considered as comparators. We did
55
56
57
58
59
60

1
2
3 not define a primary outcome for the purposes of this scoping review. We included primary
4
5 studies that used quantitative, qualitative or mixed methods. Systematic and integrative reviews
6
7 were identified for the purpose of reviewing their included studies for potential relevant studies.
8

9
10 We excluded case series, case studies, case reports, clinical practice guidelines, theses and
11
12 opinion-driven reports (editorials, non-systematic or literature/narrative reviews).
13

14
15 Three reviewers (BK, MD, and BH) performed an initial screen of titles and abstracts using a
16
17 citation screening tool. A calibration exercise was performed by the three reviewers through pilot
18
19 testing a random sample of 50 citations with consistent screening achieved ($\kappa = 0.79$) at
20
21 which point the three reviewers screened the remaining titles and abstracts. Two reviewers (BK
22
23 and MD) followed a similar procedure for identifying relevant full text studies, with good
24
25 agreement between reviewers ($\kappa = 0.78$). Disagreements were resolved by consensus or
26
27 arbitration by a third reviewer (BH).
28
29

30 31 **Charting, collating and summarizing the data**

32
33

34
35 We developed a data extraction form based on the Template for Intervention Description and
36
37 Replication (TIDierR) checklist (16) and the Effective Practice and Organization of Care
38
39 (EPOC) data collection form (17). Study characteristics (e.g. study design, country of origin,
40
41 publication year), population characteristics (e.g. CKD stage, comorbidities), and self-
42
43 management intervention characteristics (e.g. topics, format, target audience, providers, location,
44
45 dose, duration, etc.) were documented. For the study outcomes, the two reviewers (BK and MD)
46
47 independently coded each outcome into categories identified by Grey et al (e.g. behaviors,
48
49 cognitions, physiological measures, symptoms, health status, health care and other) (6). We pilot
50
51 tested the form on a random sample of 10 eligible studies and once consensus between the two
52
53 reviewers was reached, we independently abstracted data from the remaining eligible studies.
54
55
56
57
58
59

CKD self-management interventions

1
2
3 Data was categorized and reported descriptively. For qualitative studies we identified the
4 methodology and key concepts presented by the authors.
5

RESULTS**Search results**

10
11
12
13
14 From 12,583 unique citations (Figure 1) we included 50 full text studies.
15
16

Description of studies

17
18
19
20 A summary of the 50 studies included in this review is provided in Table 1. The most common
21 study designs were randomized controlled trials (RCTs) (38%). Non-RCTs consisted of quasi-
22 experimental (14%), observational (10%), pre-post intervention (26%), qualitative (10%) and
23 mixed methods (2%). The studies were conducted in 14 countries, including the United States
24 (20%), United Kingdom (14%) and Australia (12%). Most studies were published in the last 5
25 years (64%).
26
27
28
29
30
31
32
33

Patient population characteristics

34
35
36
37 The target population in most studies was CKD (72%) and 15 studies mentioned CKD plus one
38 or more associated comorbidities. The average ages of participants reported across studies were
39 50.2 to 74.3 years.
40
41
42
43
44

Description of self-management interventions

45
46
47
48 Table 2 summarizes the characteristics of the self-management interventions. Five studies
49 reported the same self-management intervention (18-22), therefore 45 interventions were
50 summarized. The most common intervention topic was diet/nutrition (64%) and the least
51 common were symptom management and lifestyle (13% and 11% respectively). The most
52
53
54
55
56
57
58
59
60

1
2
3 frequent modes of delivering the intervention were face to face (80%), multiple (i.e. more than
4 one mode) (71%) and print (64%). Electronic was the least common delivery mode (16%).
5
6 Interventions were administered by a variety of providers. The most common category of
7
8 providers was “other” (56%), which was made up of various types of health professionals and
9
10 lay people. However, the most common identifiable group of providers were nursing
11
12 professionals (49%). Patient volunteer/mentor was the least common (9%). The outpatient
13
14 setting was the most common location for providing the self-management intervention (51%),
15
16 and the inpatient setting was the least popular (2%). Many studies did not report the intervention
17
18 language (53%), but 12 languages were represented and 7 studies reported that they provided the
19
20 intervention in multiple languages.
21
22
23
24
25

26
27 In terms of intervention development, only 20% of studies mentioned the use of evidence such as
28
29 theories or frameworks. These included the transtheoretical model of behavior change, social
30
31 cognitive theory and chronic care model (23-27). Less than 1% of the studies involved patients in
32
33 the design of the intervention, where patients were interviewed regarding intervention content
34
35 (23, 28-30).
36
37
38

39 **Description of quantitative study outcomes and results**

40
41
42 Characteristics of the quantitative study outcomes are presented in Table 3. Twenty-three (46%)
43
44 studies measured physiological outcomes (i.e. laboratory tests, body composition, etc.). The least
45
46 common outcomes reported by studies were health status and health care (each 10%) and
47
48 symptoms (i.e. fatigue) (4%). Table 4 summarizes the details of the quantitative studies. We
49
50 categorized the overall study results descriptively as improved, unchanged, or worse. Many
51
52 studies had more than one outcome measure (i.e. one measure improved, another had no change)
53
54 and they were reported as mixed results. Based on this method of categorization, 89 outcomes
55
56
57
58
59
60

CKD self-management interventions

1
2
3 were reported, of which 61% improved, 20% had no change, 1% worsened, and 13% had mixed
4
5 results. Four of the results were reported as not applicable as the outcomes were not relevant. Of
6
7 the 54 outcome categories that improved, 15 were cognition, 9 were physiological measures, 8
8
9 were behaviors, 8 were individual outcomes, 5 were health status, 4 were health care, 4 were
10
11 other, and 1 was symptom management.
12
13

Description of qualitative study outcomes and results

14
15
16
17
18 Table 5 summarizes the findings from 6 qualitative studies that look at patient perspectives, one
19
20 of these being a mixed methods study. All studies used semi-structured interviews and one also
21
22 used a questionnaire. The aims of all these studies were to examine patient perspectives'
23
24 regarding the self-management interventions they were involved in. Due to the variety of
25
26 interventions (i.e. intervention topics, delivery mode and providers of the intervention) it was
27
28 difficult to summarize findings into meaningful categories. Overall, patients highlighted that
29
30 interventions needed to be individualized and tailored to their specific situations and preferences
31
32 (i.e. awareness of having CKD, stage of CKD, knowledge of the disease, access to resources,
33
34 etc.).
35
36
37
38

DISCUSSION

39
40
41
42 To our knowledge, this is the first scoping review involving patient partners to identify and
43
44 summarize self-management interventions for adults with CKD. The scoping review
45
46 methodology enabled us to systematically summarize a broad range of self-management
47
48 interventions, and describe their features. We identified 50 studies that investigated self-
49
50 management interventions for adults with CKD, with considerable variation in interventions,
51
52 outcomes assessed and results obtained (i.e. some improved and/or some worsened and/or some
53
54
55
56
57
58
59
60

1
2
3 did not change). We found that self-management interventions for CKD is an emerging area
4
5 with most studies published within the last 5 years, and may be related to the growing
6
7 recognition of the importance of incorporating patients and their families in managing their
8
9 disease to improve outcomes (7).

10
11
12
13 Our findings are similar to prior reviews reporting that the design of self-management
14
15 interventions for CKD have not been theoretically driven and have been predominately designed
16
17 by healthcare professionals without input from patients (10, 11). Patient-centred care is changing
18
19 how healthcare professionals deliver care to patients, but more importantly how patients and
20
21 their families are actively involved in self-managing their chronic conditions. Engaging patients
22
23 by having them co-design self-management interventions will ensure that patient preferences
24
25 based on their values, culture, and psychosocial needs will be addressed in the self-management
26
27 intervention (9-11). Through our current national partnership with patients, researchers and
28
29 clinicians we have the opportunity to obtain patient perspectives, along with incorporating a
30
31 behavior change theory to inform the future design of a self-management intervention for CKD.
32
33
34
35
36 Only 28% of studies that we identified included patients with CKD plus other comorbidities,
37
38 despite the common presence of comorbidities in this patient population. Less than one-quarter
39
40 of included studies provided information on how to manage comorbid conditions such as
41
42 tracking lab results and symptom management. This highlights the need to consider “whole
43
44 person care”, where the self-management intervention needs to encompass the physical, mental
45
46 and emotional needs of the patient (31, 32).
47
48
49
50
51
52
53
54
55
56
57
58
59
60

CKD self-management interventions

Forty-five different self-management interventions were identified, with one or more topics presented in a variety of formats and by a variety of providers. Symptom management and lifestyle topics were not included in many of the interventions. Based on prior work (3), non-dialysis patients with CKD have indicated that these were important topics for them in managing their CKD with an aim to slow the progression of CKD, and will be important to consider in the development of future interventions. Face to face was the most common delivery format while electronic (internet or mobile application) was least common, with many studies reporting multiple formats (i.e. face to face and printed materials). With the expansion of electronic platforms for supporting patients and providers in the uptake of evidence-based care, there is the potential to use an electronic format to support patients in self-managing their CKD and other co-morbidities (33). It is worth noting that there was variability in duration and frequency of face to face encounters, from a single session to multiple sessions over weeks to months. While varied options for in-person delivery is good if it meets the needs of the patients and their families, it may not be feasible on a larger scale due to the resources required. Only 5 studies looked at self-management health care cost-effectiveness, health care utilization and access, each measuring different end-points with mixed results. Future self-management interventions should include the essential principles to self-management (e.g. accessing relevant health information, adhering to multiple treatment protocols, changing health behaviors, shared decision making with healthcare providers) (7, 34), along with evaluation of the cost-effectiveness and resource utilization.

The majority of studies did not identify a single primary outcome but rather multiple outcomes. We found that physiological outcomes (i.e. blood pressure) were the most commonly reported and symptoms were the least mentioned. These findings demonstrate the lack of patient driven

1
2
3 outcomes that may be important to them. For example, a patient's individual health goals across
4 a variety of dimensions (i.e. symptoms, mobility, social and role function in the family or
5 community) that could possibly maximize their quality of life. Work by Tong et al highlights this
6 concept, where patients with CKD are more interested in treatment choices that influence non-
7 traditional clinical outcomes such as impact on family and lifestyle (31). A holistic approach
8 should be considered where mental and psychosocial outcomes are investigated, rather than just
9 physiological endpoints.
10
11
12
13
14
15
16
17
18
19

20 Our findings from the qualitative studies looking at patient perspectives are inconclusive because
21 of the limited number of studies and the heterogeneity of the interventions. Havas et al (9) in her
22 integrative review similarly reported a lack of research related to patient perspectives on self-
23 management in CKD. There is also a lack of qualitative studies overall, which could provide
24 valuable information regarding attitudes and challenges of self-management interventions from
25 the perspective of both providers and patients.
26
27
28
29
30
31
32
33

34 Strengths of our study include the comprehensive nature of our search, inclusion of all study
35 designs and consideration of self-management features that have not been investigated
36 previously. We also engaged patient partners in determining the research question, advising us
37 on search terms and reviewing the results to ensure we captured and reported the data
38 meaningfully. One of the main limitations was the challenge in synthesizing the data given its
39 heterogeneous nature. To address this challenge the two reviewers used two standardized tools
40 TIDieR (16) and the EPOC tool (17) to independently extract data, and independently coded the
41 outcomes into categories using the Self-and Family Management Framework (6). Also, we were
42 unable to assess the self-management outcomes in terms of sustained changes in behavior,
43 physiological, and health status. A final limitation was our inability to draw conclusions

CKD self-management interventions

1
2
3 regarding the most effective self-management intervention for adult patients with CKD, keeping
4
5 in mind our aim was to review the breadth of the current literature and present the gaps that exist.
6
7

8 Overall, we found considerable variation in self-management interventions for adults with CKD
9
10 with respect to their content and delivery, as well as the outcomes assessed and results obtained.

11
12 Major gaps in the literature include the lack of patient engagement in the design of the self-
13
14 management intervention, along with the lack of a behavioural change theory to inform their
15
16 design. Our future research will incorporate intervention frameworks to co-develop and evaluate
17
18 a self-management intervention based on a sound behavioral theory involving our national
19
20 patient-partners, specialists, primary care providers, and decision makers.
21

23

24 25 **ACKNOWLEDGEMENTS**

26
27
28 Diane Lorenzetti for providing support and direction regarding search strategies. We would also
29
30 like to thank Sarah Gil in assisting us with acquiring full text studies.
31
32

33 34 **CONFLICT OF INTEREST STATEMENT**

35
36 All authors certify that our manuscript has not been published in whole or in part elsewhere, nor
37
38 is it currently being considered for publication elsewhere. All authors declare that they have no
39
40 relevant conflicts of interest.
41
42
43

44 45 **AUTHORS' CONTRIBUTIONS**

46
47 Research idea and study design: all authors; data acquisition: MD, BK; data
48
49 analysis/interpretation: MD, BK, BRH; supervision or mentorship: BRH, PR. Each author
50
51 contributed important intellectual content during manuscript drafting and revisions and accepts

**Community: gym, grocery store, "study room"

Table 3. Summary of quantitative study outcomes*

Common outcomes	Description	Number of Studies
Physiologic measures	Changes in laboratory tests, blood pressure, body composition, functional/performance tests and cardiovascular risk.	23
Cognitions	Changes in general CKD knowledge, self-efficacy, self-management, motivation, perceived stress, anxiety and fear.	21
Behaviors	Adherence to diet, medication, physical activity, sleep, blood pressure control.	13
Individual Outcomes	QOL, well-being and general satisfaction.	11
Intervention specific	Reporting of general concepts regarding feasibility of intervention, enjoyment and interest in intervention.	9
Health care	Measurements of cost effectiveness, health care utilization and access.	5
Health status	Measurements of morbidity and mortality (i.e. time to dialysis, survival, all-cause mortality).	5
Symptoms	Changes in overall symptoms (i.e. pain, fatigue)	2

* Based on primary and distal outcomes from Grey et al (6)
 CKD – chronic kidney disease; QOL – quality of life

Table 4. Summary of quantitative studies

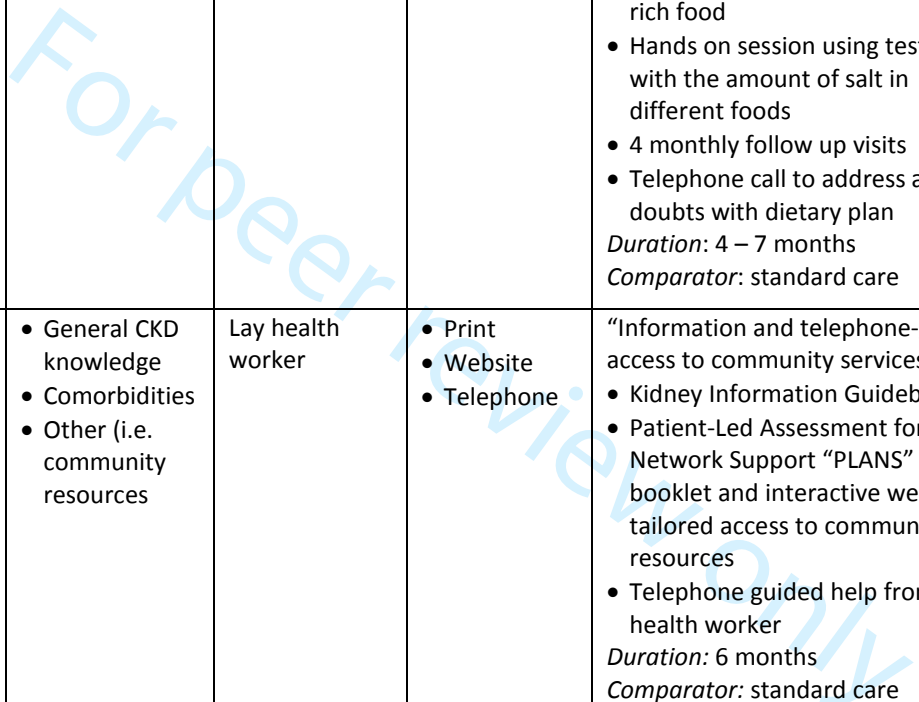

Study & Year (Reference)	Design	Target Population	Study Size Age (years)	Intervention Topic(s)	Provider(s)	Delivery Format	Description of Intervention	Study Outcomes	Study Results
RCT									
Binik 1993 (35)	RCT	Pre-RRT CKD (creatinine $\geq 350 \mu\text{mol/L}$ and rising rapidly)	204 (E = 87, C = 92, not part of education = 25) Age: 50.2	<ul style="list-style-type: none"> General CKD knowledge Diet/nutrition Modalities 	Trained research assistant	<ul style="list-style-type: none"> Print Face to face PowerPoint slides 	“Enhanced education”: <ul style="list-style-type: none"> 22-page booklet Individual slide presentation (75 mins) Duration – one session Comparator: standard care	Health Status: <ul style="list-style-type: none"> Duration between session & dialysis initiation – <i>patient in E group survived 4.6 months longer w/o requiring RRT</i> 	
Gillis 1995 (36)	RCT	CKD 3-5	840 (unclear) Age: NR	<ul style="list-style-type: none"> Diet/nutrition 	Dietician	<ul style="list-style-type: none"> Print Face to face 	“Modification of diet in renal disease”: <ul style="list-style-type: none"> “Keeping Track” booklet Monthly meeting with dietician Protein Wise Counter (lists protein content of foods) “Shopping Wise”: a guide to convenience and fast foods Visited restaurants and shops Duration – 26 months Comparator: standard protein diet	Cognitions: <ul style="list-style-type: none"> Patient reliance on dietician’s feedback, support and modeling strategies - <i>decreased over time in E group</i> 	
								Individual Outcomes: <ul style="list-style-type: none"> Top rated interventions by patients - <i>counseling, self-monitoring, protein counter</i> 	
Devins 2003 (37)	RCT	CKD (creatinine $\leq 300 \mu\text{mol/L}$ and deemed to need RRT in 6-18 months)	297 (E = 149, C = 148) Age: 58.6	<ul style="list-style-type: none"> General CKD knowledge Diet/nutrition Medication Modalities Lifestyles 	Social worker	<ul style="list-style-type: none"> Print Face to face Telephone 	“Psychoeducation”: <ul style="list-style-type: none"> 60-page booklet 90 min interactive educational intervention personalized for each patient Supportive (10 min max) phone calls Q3 weeks 	Health Status: <ul style="list-style-type: none"> Time to dialysis – <i>E group had 3 month delay in dialysis compared to C group</i>

CKD self-management interventions

ABSTRACT

Objective: To systematically identify and describe self-management interventions for adult patients with CKD.

Setting: Community-based

Participants: Adults with CKD Stages 1 – 5 (not requiring kidney replacement therapy).

Interventions: Self-management strategies for adults with CKD.

Primary and secondary outcome measures: Using a scoping review, electronic databases and grey literature were searched in October 2016 to identify self-management interventions for adults with CKD Stages 1 – 5 (not requiring kidney replacement therapy). Randomized controlled trials (RCTs), non-RCTs, qualitative and mixed method studies were included and study selection and data extraction were independently performed by two reviewers. Outcomes included behaviors, cognitions, physiological measures, symptoms, health status and health care.

Results: Fifty studies (19 RCTs, 7 quasi-experimental, 5 observational, 13 pre-post intervention, 1 mixed methods and 5 qualitative) reporting 45 interventions were included. The most common intervention topic was diet/nutrition and interventions were regularly delivered face to face. Interventions were administered by a variety of providers, with nursing professionals the most common health professional group. Cognitions (i.e. changes in general CKD knowledge, perceived self-management, and motivation) was the most frequently reported outcome domain that showed improvement. Less than 1% of the interventions were co-developed with patients and 20% were based on a theory or framework.

1
2
3 **Conclusions:** There was a wide range of self-management interventions with considerable

variability in outcomes for adults with CKD. Major gaps in the literature include lack of patient engagement in the design of the interventions, with the majority of interventions not applying a behavioral change theory to inform their development. This work highlights the need to involve patients to co-develop and evaluate a self-management intervention based on sound theories and clinical evidence.

Key words: Chronic kidney disease, scoping review, self-management, person centered-care

Strengths and limitations of this study:

- A strength of our study is that it is the first scoping review to apply the principles of patient-oriented research, where patient partners were engaged in determining the research question, advising us on search terms and reviewing the results to ensure we captured and reported the data meaningfully.
- Our scoping review is comprehensive in nature, inclusion of all study designs and consideration of self-management features that have not been investigated previously.
- Due to the heterogeneous nature of the literature, it was challenging to synthesize the data. To address this challenge the two reviewers used two standardized tools to independently extract data, and independently coded the outcomes into categories using the Self-and Family Management Framework.
- A limitation of our scoping review is that we were unable to assess the self-management outcomes in terms of sustained changes in behavior, physiological, and health status.

CKD self-management interventions

- We were unable to draw conclusions regarding the most effective self-management intervention for adult patients with CKD, keeping in mind our aim was to review the breadth of the current literature and present the gaps that exist.

For peer review only

INTRODUCTION

Chronic kidney disease (CKD) is associated with adverse health outcomes, poor quality of life and high health care costs (1). Patients with CKD often experience a number of comorbidities including diabetes, cardiovascular disease and depression (2). They must balance the medical management of their kidney disease and other chronic conditions with demands of their daily lives, including managing the emotional and psychosocial consequences of living with chronic disease. In a recent CKD research priority setting study, individuals with non-dialysis CKD, their caregivers, clinicians and policy makers identified the need to develop optimal strategies to enable patients to manage their CKD and related comorbidities to slow or prevent the progression to end-stage kidney disease (ESKD) (3). International data in research priority setting for kidney disease also highlights self-management as a top priority to prevent progression (4).

Self-management interventions aim to facilitate an individual's ability to make lifestyle changes and manage symptoms, treatment, and the physical and psychosocial consequences inherent in living with CKD and associated comorbidities (5). Self-management of CKD involves focusing on illness needs (developing knowledge, skills and confidence to manage medical aspects), activating resources (identifying and accessing resources and supports) and living with the condition (learning to cope with the condition and its impact on their lives as well as the emotional consequences of the illness) (6). Self-management requires patient engagement, however, the degree to which patients are able or willing to participate in self-management can vary, and individual and health system factors may serve as facilitators or barriers to self-management processes (7).

CKD self-management interventions

1
2
3 Despite the high prevalence of CKD and its impact on patient outcomes, there is limited
4
5 evidence on the effectiveness of self-management interventions. Prior systematic reviews (8 -
6
7 11) and three integrative reviews (12-14) found that self-management interventions were
8
9 variable in their effectiveness for managing and preventing progression of CKD. While these
10
11 reviews add to the knowledge base, they have restricted inclusion criteria (e.g. study type, patient
12
13 population) and unclear reporting strategies (i.e. describing complex self-management
14
15 interventions in detail and providing structured accounts of the interventions and outcomes). In
16
17 particular, features of self-management interventions such as person centeredness, applicability
18
19 to co-morbidities associated with CKD, physiological and non-physiological outcomes, and
20
21 application of any behavioral change theories are often lacking. Self-management interventions
22
23 need to be tailored to suit diverse patient needs and preferences, as well as the local health care
24
25 context (7). Therefore, investigating the “who”, “what” and the “how” of self-management
26
27 interventions is crucial. We used recognized literature synthesis and reporting guidelines, along
28
29 with engagement of our patient partners in determining the research question and search terms,
30
31 as well as reviewing the results to ensure we captured and reported the data meaningfully.
32
33

34
35
36
37
38 To our knowledge there is no literature synthesis that systematically and comprehensively
39
40 summarizes the breadth of evidence found in primary quantitative, qualitative and mixed
41
42 methods research regarding self-management interventions for adult patients with CKD. We
43
44 used a scoping review methodology to understand the range and types of interventions including
45
46 both educational and support interventions for CKD to inform the future design of a self-
47
48 management intervention. Specifically, we conducted a scoping review to identify and describe
49
50 self-management interventions for adult patients with CKD (stages 1 – 5; non-dialysis, non-
51
52 transplant).
53

MATERIALS AND METHODS

We used a scoping review methodology to enable us to incorporate a broad range of studies and to summarize the knowledge from a variety of sources and types of evidence (15). Our aim was to identify gaps in literature related to CKD self-management interventions and inform future research. A unique and important aspect was the involvement of “patient partners”. Through a national initiative, Canadians Seeking Solutions and Innovations to Overcome CKD (Can-SOLVE CKD), patients work side by side with researchers, clinicians and decision makers to address patient-oriented research priorities (16). Our research team includes Can-SOLVE CKD patient partners with CKD and caregivers (16). Using the Joanna Briggs Institute framework for scoping reviews we undertook the following steps: (1) identified the research question, (2) identified relevant studies, (3) completed study selection, (4) charted, collated, summarized and reported the results, and (5) consulted with our patient partners (15, 17). These steps were iterative to ensure comprehensive inclusion of the literature and continued meaningful engagement with our patient partners. This work involves identifying, reviewing and categorizing data from primary articles and does not involve human participants and is exempt from ethics approval.

Research aim

Our scoping review aimed to determine the available self-management interventions for adults aged 18 years and over and diagnosed with CKD Stages 1 – 5 (not requiring dialysis or transplant).

Search and selection of studies

We worked with an information specialist (DL) to identify key words that represented the population (CKD) and the intervention (self-management). We searched a broad range of information sources including the following online databases: MEDLINE (OVID), EMBASE, PsycINFO, Cochrane Central Register of Controlled Trials, CINAHL Plus and Cochrane Database of Systematic Reviews for published studies, with no limits on date (inception to October 2016), language, age or study design. We also searched Web of Science from 2006 – October 2016 to capture recently published meeting abstracts and summaries. Using the Canadian Agency for Drugs and Technology (CADTH) Grey Matters approach, (18) we searched Google Canada, Health Technology Assessment (HTA) agencies (Canada, Australia, Ireland, UK and US), and Clinical Trials databases (Biomed Central – ISRCTN Registry, US National Institutes of Health, ClinicalTrials.gov) during October 2016 with no language restrictions (Table S1). Our search strategy for grey literature was guided by the specific database (i.e. Google search operators, website search filters) and was completed within a single session for each search strategy to ensure consistency due to the dynamic nature of the Internet (Table S2). Two reviewers (BK and MD) also reviewed the reference lists of included studies, along with those identified in past systematic and integrative reviews of our research topic. We contacted authors of relevant protocols and conference abstracts to ascertain if their work and findings were published.

A study was included if the population involved adults with CKD (stages 1 – 5, non-dialysis, non-transplant). Self-management interventions included strategies, tools, or resources in any delivery format (print, electronic, face to face, etc.) that facilitated an individual's ability to make

1
2
3 lifestyle changes or to manage symptoms, treatment, or the physical and psychosocial
4 consequences inherent in living with CKD and other associated comorbidities. Interventions
5 targeted only at selection of treatment for ESKD (i.e. dialysis, kidney transplant) were excluded.
6
7 Other self-management interventions or standard care were considered as a comparison. We
8 included primary studies that used quantitative, qualitative or mixed methods. Systematic and
9 integrative reviews were identified for the purpose of reviewing their included studies for
10 potential relevant studies. We excluded case series, case studies, case reports, clinical practice
11 guidelines, theses and opinion-driven reports (editorials, non-systematic or literature/narrative
12 reviews).

13
14 Three reviewers (BK, MD, and BH) performed an initial screen of titles and abstracts using a
15 citation screening tool. To determine inter-rater reliability, a calibration exercise was performed
16 by the three reviewers. Pilot testing a random sample of 50 citations achieved good agreement
17 (kappa = 0.79) at which point the three reviewers screened the remaining titles and abstracts.
18
19 Two reviewers (BK and MD) followed a similar procedure for identifying relevant full text
20 studies, with good agreement between the two reviewers (kappa = 0.78). Disagreements were
21 resolved by discussion and obtaining consensus between the three reviewers.
22
23

24 **Charting, collating and summarizing the data**

25
26 We developed a data extraction form based on the Template for Intervention Description and
27 Replication (TIDierR) checklist (19). This checklist provides a template to structure accounts of
28 an intervention (e.g. goal of intervention, materials used, who delivered the intervention and
29 how, where, when and how much, and how well the intervention was delivered). We also used
30 the Effective Practice and Organization of Care (EPOC) data collection form (20) to ensure we
31 were comprehensive in extracting relevant study characteristics as outlined by Cochrane EPOC

3 group. Study characteristics (e.g. study design, country of origin, publication year), population
4 characteristics (e.g. CKD stage, comorbidities), and self-management intervention characteristics
5 (e.g. topics, format, target audience, providers, location, dose, duration, etc.) were documented.
6
7
8 For the study outcomes, the two reviewers (BK and MD) independently coded each outcome into
9
10 categories identified by Grey et al (e.g. behaviors, cognitions, physiological measures,
11
12 symptoms, health status, health care and other) (6). We pilot tested the form on a random sample
13
14 of 10 eligible studies and once consensus between the two reviewers was reached, we
15
16 independently abstracted data from the remaining eligible studies. Data was categorized and
17
18 reported descriptively (i.e. counts and frequencies). For qualitative studies we identified the
19
20 methodology and key concepts presented by the authors.
21
22

Prior	7

The most common study designs were randomized controlled trials (RCTs) (38%). Non-RCTs consisted of quasi-experimental (14%), observational (10%), pre-post intervention (26%), qualitative (10%) and mixed methods (2%). The studies were conducted in 14 countries, including the United States (20%), United Kingdom (14%) and Australia (12%). Most studies were published in the last 5 years (64%).

Patient population characteristics

The target population in most studies was CKD (72%) and 15 studies mentioned CKD plus one or more associated comorbidities. The average ages of participants reported across studies were 50.2 to 74.3 years.

Description of self-management interventions

Table 2 summarizes the characteristics of the self-management interventions. Five studies reported the same self-management intervention (21-25), therefore 45 interventions were summarized. The most common intervention topic was diet/nutrition (64%) and the least common were symptom management and lifestyle (13% and 11% respectively). The most frequent modes of delivering the intervention were face to face (80%), multiple (i.e. more than one mode) (71%) and print (64%). Electronic was the least common delivery mode (16%). Interventions were administered by a variety of providers. The most common category of providers was “other” (56%), which was made up of various types of health professionals and lay people. However, the most common identifiable group of providers were nursing professionals (49%). Patient volunteer/mentor was the least common (9%). The outpatient setting was the most common location for providing the self-management intervention (51%), and the inpatient setting was the least popular (2%). Many studies did not report the intervention language (53%), but 12 languages were represented and 7 studies reported that they provided the intervention in multiple languages.

In terms of intervention development, only 20% of studies mentioned the use of evidence such as theories or frameworks. These included the transtheoretical model of behavior change, social cognitive theory and chronic care model (26-30). Less than 1% of the studies involved patients in

CKD self-management interventions

the design of the intervention, where patients were interviewed regarding intervention content (26, 31-33).

CKD self-management interventions

Description of quantitative study outcomes and results

Characteristics of the quantitative study outcomes are presented in Table 3. Twenty-three (46%) studies measured physiological outcomes (i.e. laboratory tests, body composition, etc.). The least common outcomes reported by studies were health status and health care (each 10%) and symptoms (i.e. fatigue) (4%). Table 4 summarizes the details of the quantitative studies. We categorized the overall study results descriptively as improved, unchanged, or worse. Many studies had more than one outcome measure (e.g.. one measure improved, another had no change) and they were reported as mixed results. Based on this method of categorization, 89 outcomes were reported, of which 61% improved, 20% had no change, 1% worsened, and 13% had mixed results. Four of the results were reported as not applicable as the outcomes were not relevant. Of the 54 outcome categories that improved, 15 were cognition, 9 were physiological measures, 8 were behaviors, 8 were individual outcomes, 5 were health status, 4 were health care, 4 were intervention specific, and 1 was symptom management.

Table 3 Summary of quantitative study outcomes*

Common outcomes	Description	Number of studies	Number of studies in which outcome improved
Physiologic measures	Changes in laboratory tests, blood pressure, body composition, functional/performance tests and cardiovascular risk.	23	9
Cognitions	Changes in general CKD knowledge, self-efficacy, self-management, motivation, perceived stress, anxiety and fear.	21	15
Behaviors	Adherence to diet, medication, physical activity, sleep, blood pressure control.	13	8
Individual outcomes	QOL, well-being and general satisfaction.	11	8
Intervention specific	Reporting of general concepts regarding feasibility of intervention, enjoyment and interest in intervention.	9	4
Health care	Measurements of cost effectiveness, health care utilization and access.	5	4
Health status	Measurements of morbidity and mortality (i.e. time to dialysis, survival, all-cause mortality).	5	5
Symptoms	Changes in overall symptoms (i.e. pain, fatigue)	2	1

* Based on primary and distal outcomes from Grey et al (6)

CKD – chronic kidney disease; QOL – quality of life

Description of qualitative study outcomes and results

Table 5 summarizes the findings from 6 qualitative studies that explored patient perspectives, one of these being a mixed methods study. All studies used semi-structured interviews and one also used a questionnaire. The aims of all these studies were to examine patient perspectives' regarding the self-management interventions they were involved in. Due to the variety of interventions (e.g. intervention topics, delivery mode and providers of the intervention) it was difficult to summarize findings into meaningful categories. Overall, patients highlighted that interventions needed to be individualized and tailored to their specific situations and preferences (e.g. awareness of having CKD, stage of CKD, knowledge of the disease, access to resources, etc.).

CKD self-management interventions

Table 5 Summary of qualitative studies

Study (Reference)	Target population	Number of participants	Aim/Intervention	Methods	Summary of findings
Blickem (21)	CKD Stage 3	20	<p>“To explore the experience of patient-led assessment for network support (PLANS) from the perspectives of participants and telephone support workers.” (p.1)</p> <p>Intervention: see Table 4 Blakeman (47)</p>	Interviews and focus groups: No analytic methodology discussed	<ul style="list-style-type: none"> • Mixed reception from participants • Formulation of “health” in everyday life (i.e. participants unaware of having CKD or its significance - confused about relevance of PLANS) • Trajectories and tipping points (i.e. engagement in PLANS depended on participants’ stage of life – either could influence trying new things or disrupt routines) • Trust in networks (i.e. unwillingness to seek support, intrusive, others saw improved awareness/access to local resources; tailored support)
Heiden (69)	CKD pre-dialysis, dialysis, transplant	5	<p>To identify participant’s perspective regarding a “web application prototype to help make decisions regarding diet restrictions and phosphate binder dosage.” (p.544)</p> <p>Intervention: Website tool for patients that included 3 components – diet/fluid</p>	Interviews: no analytic methodology discussed	<ul style="list-style-type: none"> • Benefits: <ul style="list-style-type: none"> ○ Education tool increased insight and understanding ○ Assisted in tracking and choosing best food alternative ○ Decision support for binder dosage • Limitations: <ul style="list-style-type: none"> ○ Targeted users familiar with using computers ○ Users had different information needs ○ One-way communication ○ Need self-care resources in place to carry out recommendations

CKD self-management interventions

			education; diet registry; and phosphate binder decision support tool.		
Jansen (70)	CKD Stages 4 – 5	7	<p>Feasibility of “a psychosocial intervention to assist ESRD patients and their partners in integrating renal disease and treatment into daily activities, primary work and thereby increasing autonomy.” (p.280)</p> <p>Intervention: Group teaching and handbook regarding coping strategies and goals based on self-regulation, social learning and self-determination theories.</p>	Interviews: no analytic methodology discussed	<ul style="list-style-type: none"> • Benefits: <ul style="list-style-type: none"> ○ Group included pre-dialysis and dialysis patients ○ Leaders addressed individual needs, situations and questions • Limitations: <ul style="list-style-type: none"> ○ Patient preferences for information differed by stages of CKD ○ Patient schedules need to be considered when intervention offered ○ Consider offering intervention shortly after diagnosis of CKD
Thomas (33)	Type 1 or 2 DM with microalbuminuria	5 (3 face-to-face interviews)	To evaluate “whether patients understood the content of the pack and whether they could make any recommendations.”	Questionnaire and interview: no analytic methodology discussed	<ul style="list-style-type: none"> • Mixed responses • DVD – content distressing and took effort to use • Written material useful, but need to elaborate on seriousness of disease • Package helped change behavior – stop smoking, monitoring DM

CKD self-management interventions

DISCUSSION

To our knowledge, this is the first scoping review involving patients as research partners to identify and summarize self-management interventions for adults with CKD. The scoping review methodology enabled us to systematically summarize a broad range of self-management interventions, and describe their features. We identified 50 studies that investigated self-management interventions for adults with CKD, with considerable variation in interventions, outcomes assessed and results obtained (i.e. some improved and/or some worsened and/or some did not change). We found that self-management interventions for CKD is an emerging area with most studies published within the last 5 years, and may be related to the growing recognition of the importance of incorporating patients and their families in managing their disease to improve outcomes (7).

Our findings are similar to prior reviews reporting that the design of self-management interventions for CKD have not been theoretically driven and have been predominately designed by healthcare professionals without input from patients (13, 14). Person-centered care is changing how healthcare professionals deliver care to patients, but more importantly how patients and their families are actively involved in self-managing their chronic conditions (71). Engaging patients by having them co-design self-management interventions will ensure that patient preferences based on their values, culture, and psychosocial needs will be addressed in the self-management intervention (12-14). Through our current national partnership with patients, researchers and clinicians we have the opportunity to obtain patient perspectives, along with incorporating a behavior change theory to inform the future design of a self-management intervention for CKD.

CKD self-management interventions

1
2
3 Only 28% of studies that we identified included patients with CKD plus other comorbidities,
4 despite the common presence of comorbidities in this patient population. Less than one-quarter
5 of included studies provided information on how to manage comorbid conditions such as
6 tracking lab results and symptom management. This highlights the need to consider “whole
7 person care”, where the self-management intervention needs to encompass the physical, mental
8 and emotional needs of the patient (72, 73) that are important to them, as well as meeting the
9 individuals desires by collaboration between relevant providers (71).

10
11
12
13
14
15
16
17
18
19
20 Forty-five different self-management interventions were identified, with one or more topics
21 presented in a variety of formats and by a variety of providers. Symptom management and
22 lifestyle topics were not included in many of the interventions. Based on prior work (3), non-
23 dialysis patients with CKD have indicated that these were important topics for them in managing
24 their CKD with an aim to slow the progression of CKD, and will be important to consider in the
25 development of future interventions. Face to face was the most common delivery format while
26 electronic (internet or mobile application) was least common, with many studies reporting
27 multiple formats (i.e. face to face and printed materials). With the expansion of electronic
28 platforms for supporting patients and providers in the uptake of evidence-based care, there is the
29 potential to use an electronic format to support patients in self-managing their CKD and other
30 co-morbidities (74). It is worth noting that there was variability in duration and frequency of face
31 to face encounters, from a single session to multiple sessions over weeks to months. While
32 varied options for in-person delivery is good if it meets the needs of the patients and their
33 families, it may not be feasible on a larger scale due to the resources required. Only 5 studies
34 looked at self-management health care cost-effectiveness, health care utilization and access, each
35 measuring different end-points with mixed results. Future self-management interventions should

CKD self-management interventions

1
2
3 include the essential principles to self-management (e.g. accessing relevant health information,
4
5 adhering to multiple treatment protocols, changing health behaviors, shared decision making
6
7 with healthcare providers) (7, 75), along with evaluation of the cost-effectiveness and resource
8
9 utilization.

10
11
12
13 The majority of studies did not identify a single primary outcome but rather multiple outcomes.
14
15 We found that physiological outcomes (i.e. blood pressure) were the most commonly reported
16
17 and symptoms were the least mentioned. These findings demonstrate the lack of patient driven
18
19 outcomes that may be important to them. For example, a patient's individual health goals across
20
21 a variety of dimensions (i.e. symptoms, mobility, social and role function in the family or
22
23 community) that could possibly maximize their quality of life. Work by Tong et al. (2015)
24
25 highlights this concept, where patients with CKD are more interested in treatment choices that
26
27 influence non-traditional clinical outcomes such as impact on family and lifestyle (72). A holistic
28
29 approach should be considered where mental and psychosocial outcomes are investigated, rather
30
31 than just physiological endpoints.
32
33
34

35
36
37 Our findings from the qualitative studies looking at patient perspectives are inconclusive because
38
39 of the limited number of studies and the heterogeneity of the interventions. Havas et al. (2016)
40
41 similarly reported a lack of research related to patient perspectives on self-management in CKD
42
43 (12). There is also a lack of qualitative studies overall, which could provide valuable information
44
45 regarding attitudes and challenges of self-management interventions from the perspective of both
46
47 providers and patients.
48
49

50
51 Strengths of our study include the comprehensive nature of our search, inclusion of all study
52
53 designs and consideration of self-management features that have not been investigated
54
55 previously. We also engaged patient partners in determining the research question, advising us
56
57

1
2
3 on search terms, grey literature sources and reviewing the results to ensure we captured and
4 reported the data meaningfully. One of the main limitations was the challenge in synthesizing the
5 data given its heterogeneous nature. To address this challenge the two reviewers used two
6 standardized tools TIDieR (19) and the EPOC tool (20) to independently extract data, and
7 independently coded the outcomes into categories using the Self-and Family Management
8 Framework (6). Also, we were unable to assess the self-management outcomes in terms of
9 sustained changes in behavior, physiological, and health status. A final limitation was our
10 inability to draw conclusions regarding the most effective self-management intervention for adult
11 patients with CKD, keeping in mind our aim was to review the breadth of the current literature
12 and present the gaps that exist.
13
14
15
16
17
18
19
20
21
22
23
24
25

26
27 Overall, we found considerable variation in self-management interventions for adults with CKD
28 with respect to their content and delivery, as well as the outcomes assessed and results obtained.
29 Major gaps in the literature include the lack of patient engagement in the design of the self-
30 management intervention, along with the lack of a behavioral change theory to inform their
31 design. Our future research will incorporate intervention frameworks to co-develop and evaluate
32 a self-management intervention based on a sound behavioral theory involving our national
33 patient partners, specialists, primary care providers, and decision makers.

CONFLICT OF INTEREST STATEMENT

All authors certify that our manuscript has not been published in whole or in part elsewhere, nor is it currently being considered for publication elsewhere. All authors declare that they have no relevant conflicts of interest.

AUTHORS' CONTRIBUTIONS

Research idea and study design: all authors; data acquisition: MD, BK; data analysis/interpretation: MD, BK, BRH; supervision or mentorship: BRH, PR. Each author contributed important intellectual content during manuscript drafting and revisions and accepts accountability for the overall work by ensuring that questions to the accuracy or integrity of any portion of the work are appropriately investigated and resolved.

FUNDING

Ms. Maoliosa Donald is supported by Alberta SPOR Graduate Studentship in Patient-Oriented Research. Dr. Brenda Hemmelgarn is supported by the Roy and Vi Baay Chair in Kidney Research, Canadian Institutes of Health Research's Strategy for Patient-Oriented Research (SPOR). The funding organizations had no role in the design and conduct of the study; data collection, analysis and interpretation; or preparation, review or approval of the manuscript.

DATA SHARING STATEMENT

The following data will be available, study protocol and analysis plan to anyone who wishes to access the data and will be available immediately following publication from the corresponding author.

CKD self-management interventions

ABSTRACT

Objective: To systematically identify and describe self-management interventions for adult patients with CKD.

Setting: Community-based

Participants: Adults with CKD Stages 1 – 5 (not requiring kidney replacement therapy).

Interventions: Self-management strategies for adults with CKD.

Primary and secondary outcome measures: Using a scoping review, electronic databases and grey literature were searched in October 2016 to identify self-management interventions for adults with CKD Stages 1 – 5 (not requiring kidney replacement therapy). Randomized controlled trials (RCTs), non-RCTs, qualitative and mixed method studies were included and study selection and data extraction were independently performed by two reviewers. Outcomes included behaviors, cognitions, physiological measures, symptoms, health status and health care.

Results: Fifty studies (19 RCTs, seven quasi-experimental, five observational, 13 pre-post intervention, one mixed methods and five qualitative) reporting 45 interventions were included. The most common intervention topic was diet/nutrition and interventions were regularly delivered face to face. Interventions were administered by a variety of providers, with nursing professionals the most common health professional group. Cognitions (i.e. changes in general CKD knowledge, perceived self-management, and motivation) was the most frequently reported outcome domain that showed improvement. Less than 1% of the interventions were co-developed with patients and 20% were based on a theory or framework.

1
2
3 **Conclusions:** There was a wide range of self-management interventions with considerable

variability in outcomes for adults with CKD. Major gaps in the literature include lack of patient engagement in the design of the interventions, with the majority of interventions not applying a behavioral change theory to inform their development. This work highlights the need to involve patients to co-develop and evaluate a self-management intervention based on sound theories and clinical evidence.

Key words: Chronic kidney disease, scoping review, self-management, person centered-care

Strengths and limitations of this study:

- A strength of our study is that it is the first scoping review to apply the principles of patient-oriented research, where patient partners were engaged in determining the research question, advising us on search terms and reviewing the results to ensure we captured and reported the data meaningfully.
- Our scoping review is comprehensive in nature, inclusion of all study designs and consideration of self-management features that have not been investigated previously.
- Due to the heterogeneous nature of the literature, it was challenging to synthesize the data. To address this challenge the two reviewers used two standardized tools to independently extract data, and independently coded the outcomes into categories using the Self-and Family Management Framework.
- A limitation of our scoping review is that we were unable to assess the self-management outcomes in terms of sustained changes in behavior, physiological, and health status.

CKD self-management interventions

- We were unable to draw conclusions regarding the most effective self-management intervention for adult patients with CKD, keeping in mind our aim was to review the breadth of the current literature and present the gaps that exist.

For peer review only

INTRODUCTION

Chronic kidney disease (CKD) is associated with adverse health outcomes, poor quality of life and high health care costs (1). Patients with CKD often experience a number of comorbidities including diabetes, cardiovascular disease and depression (2). They must balance the medical management of their kidney disease and other chronic conditions with demands of their daily lives, including managing the emotional and psychosocial consequences of living with chronic disease. In a recent CKD research priority setting study, individuals with non-dialysis CKD, their caregivers, clinicians and policy makers identified the need to develop optimal strategies to enable patients to manage their CKD and related comorbidities to slow or prevent the progression to end-stage kidney disease (ESKD) (3). International data in research priority setting for kidney disease also highlights self-management as a top priority to prevent progression (4).

Self-management interventions aim to facilitate an individual's ability to make lifestyle changes and manage symptoms, treatment, and the physical and psychosocial consequences inherent in living with CKD and associated comorbidities (5). Self-management of CKD involves focusing on illness needs (developing knowledge, skills and confidence to manage medical aspects), activating resources (identifying and accessing resources and supports) and living with the condition (learning to cope with the condition and its impact on their lives as well as the emotional consequences of the illness) (6). Self-management requires patient engagement, however, the degree to which patients are able or willing to participate in self-management can vary, and individual and health system factors may serve as facilitators or barriers to self-management processes (7).

CKD self-management interventions

1
2
3 Despite the high prevalence of CKD and its impact on patient outcomes, there is limited
4
5 evidence on the effectiveness of self-management interventions. Prior systematic reviews (8 -
6
7 11) and three integrative reviews (12-14) found that self-management interventions were
8
9 variable in their effectiveness for managing and preventing progression of CKD. While these
10
11 reviews add to the knowledge base, they have restricted inclusion criteria (e.g. study type, patient
12
13 population) and unclear reporting strategies (i.e. describing complex self-management
14
15 interventions in detail and providing structured accounts of the interventions and outcomes). In
16
17 particular, features of self-management interventions such as person centeredness, applicability
18
19 to co-morbidities associated with CKD, physiological and non-physiological outcomes, and
20
21 application of any behavioral change theories are often lacking. Self-management interventions
22
23 need to be tailored to suit diverse patient needs and preferences, as well as the local health care
24
25 context (7). Therefore, investigating the “who”, “what” and the “how” of self-management
26
27 interventions is crucial. We used recognized literature synthesis and reporting guidelines, along
28
29 with engagement of our patient partners in determining the research question and search terms,
30
31 as well as reviewing the results to ensure we captured and reported the data meaningfully.
32
33

34
35
36
37
38 To our knowledge there is no literature synthesis that systematically and comprehensively
39
40 summarizes the breadth of evidence found in primary quantitative, qualitative and mixed
41
42 methods research regarding self-management interventions for adult patients with CKD. We
43
44 used a scoping review methodology to understand the range and types of interventions including
45
46 both educational and support interventions for CKD to inform the future design of a self-
47
48 management intervention. Specifically, we conducted a scoping review to identify and describe
49
50 self-management interventions for adult patients with CKD (stages 1 – 5; non-dialysis, non-
51
52 transplant).
53
54
55
56
57
58
59
60

MATERIALS AND METHODS

We used a scoping review methodology to enable us to incorporate a broad range of studies and to summarize the knowledge from a variety of sources and types of evidence (15). Our aim was to identify gaps in literature related to CKD self-management interventions and inform future research. A unique and important aspect was the involvement of “patient partners”. Through a national initiative, Canadians Seeking Solutions and Innovations to Overcome CKD (Can-SOLVE CKD), patients work side by side with researchers, clinicians and decision makers to address patient-oriented research priorities (16). Our research team includes Can-SOLVE CKD patient partners with CKD and caregivers (16). Using the Joanna Briggs Institute framework for scoping reviews we undertook the following steps: (1) identified the research question, (2) identified relevant studies, (3) completed study selection, (4) charted, collated, summarized and reported the results, and (5) consulted with our patient partners (15, 17). These steps were iterative to ensure comprehensive inclusion of the literature and continued meaningful engagement with our patient partners. This work involves identifying, reviewing and categorizing data from primary articles and does not involve human participants and is exempt from ethics approval.

Research aim

Our scoping review aimed to determine the available self-management interventions for adults aged 18 years and over and diagnosed with CKD Stages 1 – 5 (not requiring dialysis or transplant).

Search and selection of studies

We worked with an information specialist (DL) to identify key words that represented the population (CKD) and the intervention (self-management). We searched a broad range of information sources including the following online databases: MEDLINE (OVID), EMBASE, PsycINFO, Cochrane Central Register of Controlled Trials, CINAHL Plus and Cochrane Database of Systematic Reviews for published studies, with no limits on date (inception to October 2016), language, age or study design. We also searched Web of Science from 2006 – October 2016 to capture recently published meeting abstracts and summaries. Using the Canadian Agency for Drugs and Technology (CADTH) Grey Matters approach, (18) we searched Google Canada, Health Technology Assessment (HTA) agencies (Canada, Australia, Ireland, UK and US), and Clinical Trials databases (Biomed Central – ISRCTN Registry, US National Institutes of Health, ClinicalTrials.gov) during October 2016 with no language restrictions (Table S1). Our search strategy for grey literature was guided by the specific database (i.e. Google search operators, website search filters) and was completed within a single session for each search strategy to ensure consistency due to the dynamic nature of the Internet (Table S2). Two reviewers (BK and MD) also reviewed the reference lists of included studies, along with those identified in past systematic and integrative reviews of our research topic. We contacted authors of relevant protocols and conference abstracts to ascertain if their work and findings were published.

A study was included if the population involved adults with CKD (stages 1 – 5, non-dialysis, non-transplant). Self-management interventions included strategies, tools, or resources in any delivery format (print, electronic, face to face, etc.) that facilitated an individual's ability to make

1
2
3 lifestyle changes or to manage symptoms, treatment, or the physical and psychosocial
4 consequences inherent in living with CKD and other associated comorbidities. Interventions
5 targeted only at selection of treatment for ESKD (i.e. dialysis, kidney transplant) were excluded.
6
7 Other self-management interventions or standard care were considered as a comparison. We
8 included primary studies that used quantitative, qualitative or mixed methods. Systematic and
9 integrative reviews were identified for the purpose of reviewing their included studies for
10 potential relevant studies. We excluded case series, case studies, case reports, clinical practice
11 guidelines, theses and opinion-driven reports (editorials, non-systematic or literature/narrative
12 reviews).

13
14 Three reviewers (BK, MD, and BH) performed an initial screen of titles and abstracts using a
15 citation screening tool. To determine inter-rater reliability, a calibration exercise was performed
16 by the three reviewers. Pilot testing a random sample of 50 citations achieved good agreement
17 (kappa = 0.79) at which point the three reviewers screened the remaining titles and abstracts.
18
19 Two reviewers (BK and MD) followed a similar procedure for identifying relevant full text
20 studies, with good agreement between the two reviewers (kappa = 0.78). Disagreements were
21 resolved by discussion and obtaining consensus between the three reviewers.
22
23

24 **Charting, collating and summarizing the data**

25
26 We developed a data extraction form based on the Template for Intervention Description and
27 Replication (TIDierR) checklist (19). This checklist provides a template to structure accounts of
28 an intervention (e.g. goal of intervention, materials used, who delivered the intervention and
29 how, where, when and how much, and how well the intervention was delivered). We also used
30 the Effective Practice and Organization of Care (EPOC) data collection form (20) to ensure we
31 were comprehensive in extracting relevant study characteristics as outlined by Cochrane EPOC

3 group. Study characteristics (e.g. study design, country of origin, publication year), population
4 characteristics (e.g. CKD stage, comorbidities), and self-management intervention characteristics
5 (e.g. topics, format, target audience, providers, location, dose, duration, etc.) were documented.
6
7
8 For the study outcomes, the two reviewers (BK and MD) independently coded each outcome into
9 categories identified by Grey et al (e.g. behaviors, cognitions, physiological measures,
10 symptoms, health status, health care and other) (6). We pilot tested the form on a random sample
11 of 10 eligible studies and once consensus between the two reviewers was reached, we
12 independently abstracted data from the remaining eligible studies. Data was categorized and
13 reported descriptively (i.e. counts and frequencies). For qualitative studies we identified the

Brazil	1
Denmark	1
Korea	1
Year of publication	
2012 – 2016	32
2007 – 2011	11
Prior	7

The most common study designs were randomized controlled trials (RCTs) (38%). Non-RCTs consisted of quasi-experimental (14%), observational (10%), pre-post intervention (26%), qualitative (10%) and mixed methods (2%). The studies were conducted in 14 countries, including the United States (20%), United Kingdom (14%) and Australia (12%). Most studies were published in the last five years (64%).

Patient population characteristics

The target population in most studies was CKD (72%) and 15 studies mentioned CKD plus one or more associated comorbidities. The average ages of participants reported across studies were 50.2 to 74.3 years.

Description of self-management interventions

Table 2 summarizes the characteristics of the self-management interventions. Five studies reported the same self-management intervention (21-25), therefore 45 interventions were summarized. The most common intervention topic was diet/nutrition (64%) and the least common were symptom management and lifestyle (13% and 11% respectively). The most frequent modes of delivering the intervention were face to face (80%), multiple (i.e. more than one mode) (71%) and print (64%). Electronic was the least common delivery mode (16%). Interventions were administered by a variety of providers. The most common category of providers was “other” (56%), which was made up of various types of health professionals and lay people. However, the most common identifiable group of providers were nursing professionals (49%). Patient volunteer/mentor was the least common (9%). The outpatient setting was the most common location for providing the self-management intervention (51%), and the inpatient setting was the least popular (2%). Many studies did not report the intervention language (53%), but 12 languages were represented and seven studies reported that they provided the intervention in multiple languages.

In terms of intervention development, only 20% of studies mentioned the use of evidence such as theories or frameworks. These included the transtheoretical model of behavior change, social cognitive theory and chronic care model (26-30). Less than 1% of the studies involved patients in

CKD self-management interventions

the design of the intervention, where patients were interviewed regarding intervention content (26, 31-33).

CKD self-management interventions

Description of quantitative study outcomes and results

Characteristics of the quantitative study outcomes are presented in Table 3. Twenty-three (46%) studies measured physiological outcomes (i.e. laboratory tests, body composition, etc.). The least common outcomes reported by studies were health status and health care (each 10%) and symptoms (i.e. fatigue) (4%). Table 4 summarizes the details of the quantitative studies. We categorized the overall study results descriptively as improved, unchanged, or worse. Many studies had more than one outcome measure (e.g. one measure improved, another had no change) and they were reported as mixed results. Based on this method of categorization, 89 outcomes were reported, of which 61% improved, 20% had no change, 1% worsened, and 13% had mixed results. Four of the results were reported as not applicable as the outcomes were not relevant. Of the 54 outcome categories that improved, 15 were cognition, nine were physiological measures, eight were behaviors, eight were individual outcomes, five were health status, four were health care, four were intervention specific, and one was symptom management.

Table 3 Summary of quantitative study outcomes*

Common outcomes	Description	Number of studies	Number of studies in which outcome improved
Physiologic measures	Changes in laboratory tests, blood pressure, body composition, functional/performance tests and cardiovascular risk.	23	9
Cognitions	Changes in general CKD knowledge, self-efficacy, self-management, motivation, perceived stress, anxiety and fear.	21	15
Behaviors	Adherence to diet, medication, physical activity, sleep, blood pressure control.	13	8
Individual outcomes	QOL, well-being and general satisfaction.	11	8
Intervention specific	Reporting of general concepts regarding feasibility of intervention, enjoyment and interest in intervention.	9	4
Health care	Measurements of cost effectiveness, health care utilization and access.	5	4
Health status	Measurements of morbidity and mortality (i.e. time to dialysis, survival, all-cause mortality).	5	5
Symptoms	Changes in overall symptoms (i.e. pain, fatigue)	2	1

* Based on primary and distal outcomes from Grey et al (6)

CKD – chronic kidney disease; QOL – quality of life

CKD self-management interventions

Description of qualitative study outcomes and results

Table 5 summarizes the findings from six qualitative studies that explored patient perspectives, one of these being a mixed methods study. All studies used semi-structured interviews and one also used a questionnaire. The aims of all these studies were to examine patient perspectives' regarding the self-management interventions they were involved in. Due to the variety of interventions (e.g. intervention topics, delivery mode and providers of the intervention) it was difficult to summarize findings into meaningful categories. Overall, patients highlighted that interventions needed to be individualized and tailored to their specific situations and preferences (e.g. awareness of having CKD, stage of CKD, knowledge of the disease, access to resources, etc.).

CKD self-management interventions

Table 5 Summary of qualitative studies

Study (Reference)	Target population	Number of participants	Aim/Intervention	Methods	Summary of findings
Blickem (21)	CKD Stage 3	20	<p>“To explore the experience of patient-led assessment for network support (PLANS) from the perspectives of participants and telephone support workers.” (p.1)</p> <p>Intervention: see Table 4 Blakeman (47)</p>	Interviews and focus groups: No analytic methodology discussed	<ul style="list-style-type: none"> • Mixed reception from participants • Formulation of “health” in everyday life (i.e. participants unaware of having CKD or its significance - confused about relevance of PLANS) • Trajectories and tipping points (i.e. engagement in PLANS depended on participants’ stage of life – either could influence trying new things or disrupt routines) • Trust in networks (i.e. unwillingness to seek support, intrusive, others saw improved awareness/access to local resources; tailored support)
Heiden (69)	CKD pre-dialysis, dialysis, transplant	5	<p>To identify participant’s perspective regarding a “web application prototype to help make decisions regarding diet restrictions and phosphate binder dosage.” (p.544)</p> <p>Intervention: Website tool for patients that included 3 components – diet/fluid</p>	Interviews: no analytic methodology discussed	<ul style="list-style-type: none"> • Benefits: <ul style="list-style-type: none"> ○ Education tool increased insight and understanding ○ Assisted in tracking and choosing best food alternative ○ Decision support for binder dosage • Limitations: <ul style="list-style-type: none"> ○ Targeted users familiar with using computers ○ Users had different information needs ○ One-way communication ○ Need self-care resources in place to carry out recommendations

CKD self-management interventions

			education; diet registry; and phosphate binder decision support tool.		
Jansen (70)	CKD Stages 4 – 5	7	<p>Feasibility of “a psychosocial intervention to assist ESRD patients and their partners in integrating renal disease and treatment into daily activities, primary work and thereby increasing autonomy.” (p.280)</p> <p>Intervention: Group teaching and handbook regarding coping strategies and goals based on self-regulation, social learning and self-determination theories.</p>	Interviews: no analytic methodology discussed	<ul style="list-style-type: none"> • Benefits: <ul style="list-style-type: none"> ○ Group included pre-dialysis and dialysis patients ○ Leaders addressed individual needs, situations and questions • Limitations: <ul style="list-style-type: none"> ○ Patient preferences for information differed by stages of CKD ○ Patient schedules need to be considered when intervention offered ○ Consider offering intervention shortly after diagnosis of CKD
Thomas (33)	Type 1 or 2 DM with microalbuminuria	5 (3 face-to-face interviews)	To evaluate “whether patients understood the content of the pack and whether they could make any recommendations.”	Questionnaire and interview: no analytic methodology discussed	<ul style="list-style-type: none"> • Mixed responses • DVD – content distressing and took effort to use • Written material useful, but need to elaborate on seriousness of disease • Package helped change behavior – stop smoking, monitoring DM

CKD self-management interventions

			(p.275) Intervention: See Table 4 Thomas (30)		
Williams (22)	CKD Stages 2 – 4 with diabetes and cardiovascular disease	26	“Examine the perceptions of a group of CALD participants with comorbid diabetes, chronic kidney disease and cardiovascular disease ... using an intervention to influence their medication self-efficacy.” (p. 1271) Intervention: see Table 4 Williams (44)	Interviews: Ritchie and Spencer thematic approach	<ul style="list-style-type: none"> • Attitudes towards taking medications (i.e. appreciate importance of taking; medication burden; concern with the number of medications, effectiveness and side effects of medications) • Having to take medications (i.e. behaviors and family support to assist taking medications; forgetting and non-adherent; motivation to take to prevent becoming worse) • Impediments to chronic illness medication self-efficacy (i.e. lack of knowledge regarding medication; strong faith in physician’s advice; multiple medications too overwhelming; cost)
Williams (23)	CKD Stages 2 – 4, with coexisting diabetes and hypertension	39	Individual perceptions of a “telephone call using a motivational interviewing approach to improve medication adherence in participants with co-existing diabetes, CKD and hypertension.”	Interviews: Ritchie and Spencer thematic approach	<ul style="list-style-type: none"> • Importance of health (i.e. determined the degree of health behavior; altered medications or use of alternative medicine to control health) • Perceived seriousness of disease (i.e. thinking about mortality; comorbidities complicate care; acute illness with chronic conditions) • Perceived threat of disease (i.e. want to learn about disease control earlier; symptom management; looking for reasons to explain why ill)

DISCUSSION

To our knowledge, this is the first scoping review involving patients as research partners to identify and summarize self-management interventions for adults with CKD. The scoping review methodology enabled us to systematically summarize a broad range of self-management interventions, and describe their features. We identified 50 studies that investigated self-management interventions for adults with CKD, with considerable variation in interventions, outcomes assessed and results obtained (i.e. some improved and/or some worsened and/or some did not change). We found that self-management interventions for CKD is an emerging area with most studies published within the last five years, and may be related to the growing recognition of the importance of incorporating patients and their families in managing their disease to improve outcomes (7).

Our findings are similar to prior reviews reporting that the design of self-management interventions for CKD have not been theoretically driven and have been predominately designed by healthcare professionals without input from patients (13, 14). Person-centered care is changing how healthcare professionals deliver care to patients, but more importantly how patients and their families are actively involved in self-managing their chronic conditions (71). Engaging patients by having them co-design self-management interventions will ensure that patient preferences based on their values, culture, and psychosocial needs will be addressed in the self-management intervention (12-14). Through our current national partnership with patients, researchers and clinicians we have the opportunity to obtain patient perspectives, along with incorporating a behavior change theory to inform the future design of a self-management intervention for CKD.

CKD self-management interventions

1
2
3 Only 28% of studies that we identified included patients with CKD plus other comorbidities,
4 despite the common presence of comorbidities in this patient population. Less than one-quarter
5 of included studies provided information on how to manage comorbid conditions such as
6 tracking lab results and symptom management. This highlights the need to consider “whole
7 person care”, where the self-management intervention needs to encompass the physical, mental
8 and emotional needs of the patient (72, 73) that are important to them, as well as meeting the
9 individuals desires by collaboration between relevant providers (71).

10
11
12
13
14
15
16
17
18
19
20 Forty-five different self-management interventions were identified, with one or more topics
21 presented in a variety of formats and by a variety of providers. Symptom management and
22 lifestyle topics were not included in many of the interventions. Based on prior work (3), non-
23 dialysis patients with CKD have indicated that these were important topics for them in managing
24 their CKD with an aim to slow the progression of CKD, and will be important to consider in the
25 development of future interventions. Face to face was the most common delivery format while
26 electronic (internet or mobile application) was least common, with many studies reporting
27 multiple formats (i.e. face to face and printed materials). With the expansion of electronic
28 platforms for supporting patients and providers in the uptake of evidence-based care, there is the
29 potential to use an electronic format to support patients in self-managing their CKD and other
30 co-morbidities (74). It is worth noting that there was variability in duration and frequency of face
31 to face encounters, from a single session to multiple sessions over weeks to months. While
32 varied options for in-person delivery is good if it meets the needs of the patients and their
33 families, it may not be feasible on a larger scale due to the resources required. Only five studies
34 looked at self-management health care cost-effectiveness, health care utilization and access, each
35 measuring different end-points with mixed results. Future self-management interventions should

CKD self-management interventions

1
2
3 include the essential principles to self-management (e.g. accessing relevant health information,
4 adhering to multiple treatment protocols, changing health behaviors, shared decision making
5 with healthcare providers) (7, 75), along with evaluation of the cost-effectiveness and resource
6 utilization.
7
8
9

10
11
12
13 The majority of studies did not identify a single primary outcome but rather multiple outcomes.
14
15 We found that physiological outcomes (i.e. blood pressure) were the most commonly reported
16 and symptoms were the least mentioned. These findings demonstrate the lack of patient driven
17 outcomes that may be important to them. For example, a patient's individual health goals across
18 a variety of dimensions (i.e. symptoms, mobility, social and role function in the family or
19 community) that could possibly maximize their quality of life. Work by Tong et al. (2015)
20 highlights this concept, where patients with CKD are more interested in treatment choices that
21 influence non-traditional clinical outcomes such as impact on family and lifestyle (72). A holistic
22 approach should be considered where mental and psychosocial outcomes are investigated, rather
23 than just physiological endpoints.
24
25
26
27
28
29
30
31
32
33
34
35

36
37 Our findings from the qualitative studies looking at patient perspectives are inconclusive because
38 of the limited number of studies and the heterogeneity of the interventions. Havas et al. (2016)
39 similarly reported a lack of research related to patient perspectives on self-management in CKD
40 (12). There is also a lack of qualitative studies overall, which could provide valuable information
41 regarding attitudes and challenges of self-management interventions from the perspective of both
42 providers and patients.
43
44
45
46
47
48
49
50

51 Strengths of our study include the comprehensive nature of our search, inclusion of all study
52 designs and consideration of self-management features that have not been investigated
53 previously. We also engaged patient partners in determining the research question, advising us
54
55
56
57
58
59
60

1
2
3 on search terms, grey literature sources and reviewing the results to ensure we captured and
4 reported the data meaningfully. One of the main limitations was the challenge in synthesizing the
5 data given its heterogeneous nature. To address this challenge the two reviewers used two
6 standardized tools TIDieR (19) and the EPOC tool (20) to independently extract data, and
7 independently coded the outcomes into categories using the Self-and Family Management
8 Framework (6). Also, we were unable to assess the self-management outcomes in terms of
9 sustained changes in behavior, physiological, and health status. A final limitation was our
10 inability to draw conclusions regarding the most effective self-management intervention for adult
11 patients with CKD, keeping in mind our aim was to review the breadth of the current literature
12 and present the gaps that exist.
13
14
15
16
17
18
19
20
21
22
23
24
25

26
27 Overall, we found considerable variation in self-management interventions for adults with CKD
28 with respect to their content and delivery, as well as the outcomes assessed and results obtained.
29 Major gaps in the literature include the lack of patient engagement in the design of the self-
30 management intervention, along with the lack of a behavioral change theory to inform their
31 design. Our future research will incorporate intervention frameworks to co-develop and evaluate
32 a self-management intervention based on a sound behavioral theory involving our national
33 patient partners, specialists, primary care providers, and decision makers.

CONFLICT OF INTEREST STATEMENT

All authors certify that our manuscript has not been published in whole or in part elsewhere, nor is it currently being considered for publication elsewhere. All authors declare that they have no relevant conflicts of interest.

AUTHORS' CONTRIBUTIONS

MD, BK, HB, SS, PR, GH, AT, AG, BW, CL, CL, LH, MN, MJ, ME, NF, SB, SS and HRB contributed to the research idea and study design. MD and BK acquired the data. MD, BK and BRH completed data analysis and interpretation. MD, BK, HB, SS, PR, GH, AT, AG, BW, CL, CL, LH, MN, MJ, ME, NF, SB, SS and HRB contributed important intellectual content during manuscript drafting and revisions. All authors read and approved the final manuscript. BRH and PR provided mentorship.

FUNDING

Ms. Maoliosa Donald is a recipient of the 2016 Alberta SPOR Graduate Studentships in Patient-Oriented Research. Alberta SPOR Graduate Studentships in Patient-Oriented Research are jointly funded by Alberta Innovates and the Canadian Institute of Health Research. Dr. Brenda Hemmelgarn is supported by the Roy and Vi Baay Chair in Kidney Research, Canadian Institutes of Health Research's Strategy for Patient-Oriented Research (SPOR). The funding organizations had no role in the design and conduct of the study; data collection, analysis and interpretation; or preparation, review or approval of the manuscript.

DATA SHARING STATEMENT

The following data will be available, study protocol and analysis plan to anyone who wishes to access the data and will be available immediately following publication from the corresponding author.

Limited to first 10 webpages in Google for each search strategy	
October 02, 2016 at 2:30 pm	
Search Terms	
1	“Chronic kidney disease-transplant self-management”
2	“Self-management in chronic kidney disease” (Google suggestion)
3	“self-efficacy and self-management behaviors in patients with chronic kidney disease” (Google suggestion)
Total hits: 110	
Articles/abstracts/theses/trials: 58	
Other (websites, reports, documents, etc.): 52	
Grey Literature – Google Canada	
Limited to first 10 webpages in Google for each search strategy	
October 21, 2016 at 1:30 pm	
Search Terms	
1	“chronic kidney disease” and “psychological” or “psychosocial” or “psycho-educational” interventions and “Self-management in chronic kidney disease”
2	“psychological effects of dialysis” (Google suggestion) – NOT RELEVANT
3	“chronic kidney disease” and “behavioral intervention” or “health behaviors”
Total hits: 29	
Articles/abstracts/theses/trials: 18	
Other (websites, reports, documents, etc.): 11	
Grey Literature – CADTH Grey Matters	
Databases: HTA agencies, Clinical trials, Databases (free), Other	
October 03, 2016 at 9:30 am	
Search Terms	
1	“Chronic kidney disease self-management”
2	“Chronic kidney disease”
Total hits:	
HTA Agencies: 28 databases	
Clinical Trials: 4 databases	
Databases (free): 4 databases	
Other: 1 database	

***Note:** No search in CADTH Grey Matters for “psychological” or “psychosocial” or “psycho-educational interventions” or “behavioral intervention” or “health behaviors” since “chronic kidney disease” was the main concept and thus would include all concepts related to any type of intervention.

PRISMA 2009 Checklist

Section/topic	#	Checklist item	Reported on page #
TITLE			
Title	1	Identify the report as a systematic review, meta-analysis, or both.	1
ABSTRACT			
Structured summary	2	Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number.	2
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of what is already known.	5
Objectives	4	Provide an explicit statement of questions being addressed with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	7
METHODS			
Protocol and registration	5	Indicate if a review protocol exists, if and where it can be accessed (e.g., Web address), and, if available, provide registration information including registration number.	N/A
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale.	8
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	8
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	Tables S1, S2
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	8
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	9
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	9
Risk of bias in individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	N/A
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means).	N/A
Synthesis of results	14	Describe the methods of handling data and combining results of studies, if done, including measures of consistency (e.g., I ²) for each meta-analysis.	N/A

PRISMA 2009 Checklist

Page 1 of 2

Section/topic	#	Checklist item	Reported on page #
Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	N/A
Additional analyses	16	Describe methods of additional analyses (e.g., sensitivity or subgroup analyses, meta-regression), if done, indicating which were pre-specified.	N/A
RESULTS			
Study selection	17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram.	Figure 1
Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	Table 1, 2, 3, 4, 5
Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment (see item 12).	N/A
Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: (a) simple summary data for each intervention group (b) effect estimates and confidence intervals, ideally with a forest plot.	N/A
Synthesis of results	21	Present results of each meta-analysis done, including confidence intervals and measures of consistency.	N/A
Risk of bias across studies	22	Present results of any assessment of risk of bias across studies (see Item 15).	N/A
Additional analysis	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	N/A
DISCUSSION			
Summary of evidence	24	Summarize the main findings including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy makers).	37
Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review-level (e.g., incomplete retrieval of identified research, reporting bias).	39
Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	40
FUNDING			
Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review.	41
