Selected details of the reconstruction of the histological slices

Detailed description of the coarse-to-fine reconstruction step

The coarse-scale alignment involved the blockface image stack which is a spatially consistent 3D image of the brain just before sectioning. Since every stained section corresponds to a blockface image, to recover the anatomical shape of the brain, images of individual stained sections were aligned to their blockface counterparts yielding a series of coarse transformations.

The fine-scale reconstruction was performed by sequentially aligning sections starting with sections located centrally in the image stack (sections no. 160 and 150 for Nissl- and myelin-stained sections, respectively) towards either end of the stack. Red image channels of both image stacks were extracted and smoothed with 5×5 pixels median filter and the registration was performed with cross correlation as an image similarity metric. This resulted in a series of fine rigid transformations.

Finally, the transformations obtained in both steps were merged by combining the high-frequency component of the fine-scale transformation with the coarse-scale alignment. This was done by Gaussian smoothing (σ = 5 sections) of individual parameters of the fine-scale transformation (translation and rotation angle) across the *z* (stack) dimension, filtering them out, and combining with the parameters of the coarse-scale registration. The image stack was then transformed accordingly and passed to the deformable reconstruction routine.

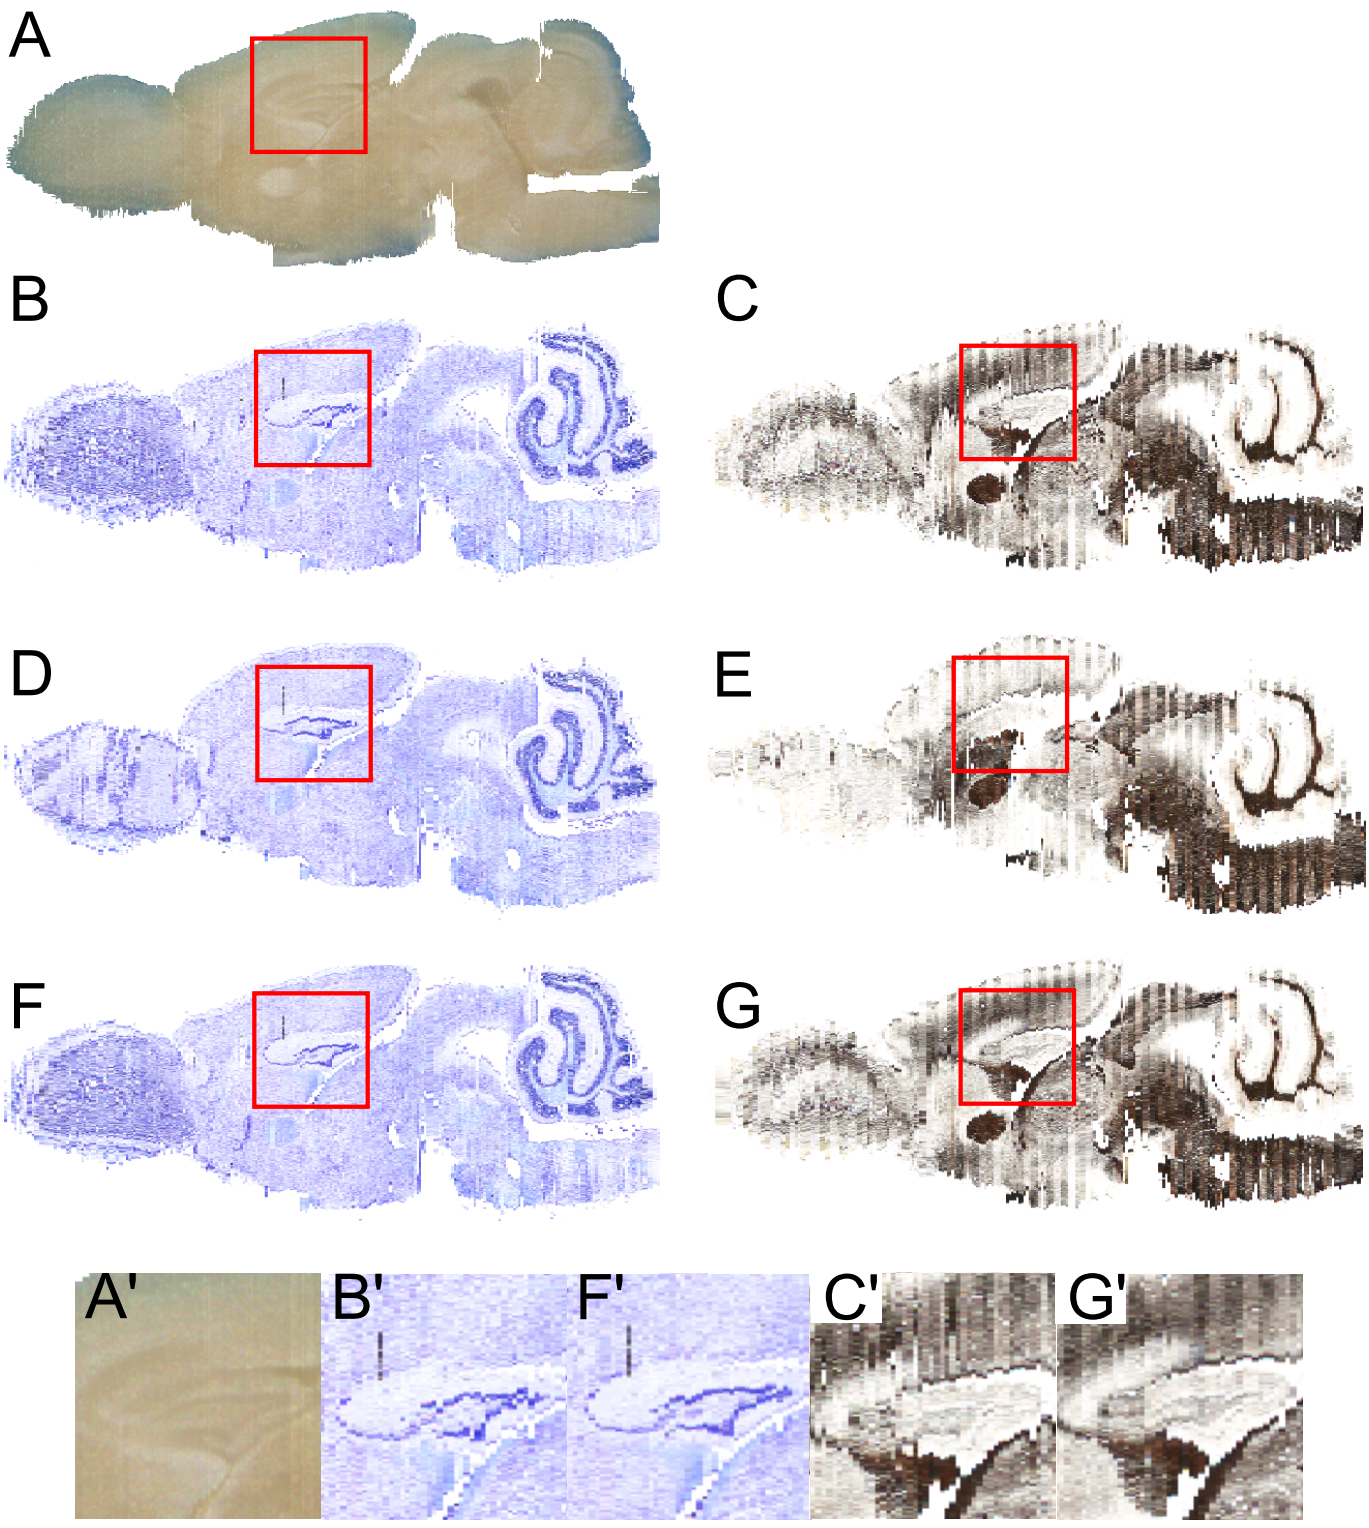

Figure S1: Comparison of the results of the rigid reconstruction of the 3D brain images based on the series of sections stained with the Nissl method and for melinated fibres. Digital saggital cross-sections through the image at various stages of the reconstruction: A) Reference blockface image; B,C) Coarse-stage reconstructions; D,E) Fine-stage reconstructions; F,G) The result of merging the coarse- and fine-stage transformations; A'-G') Magnification of the regions denoted with the red rectangles on the panels A-G.

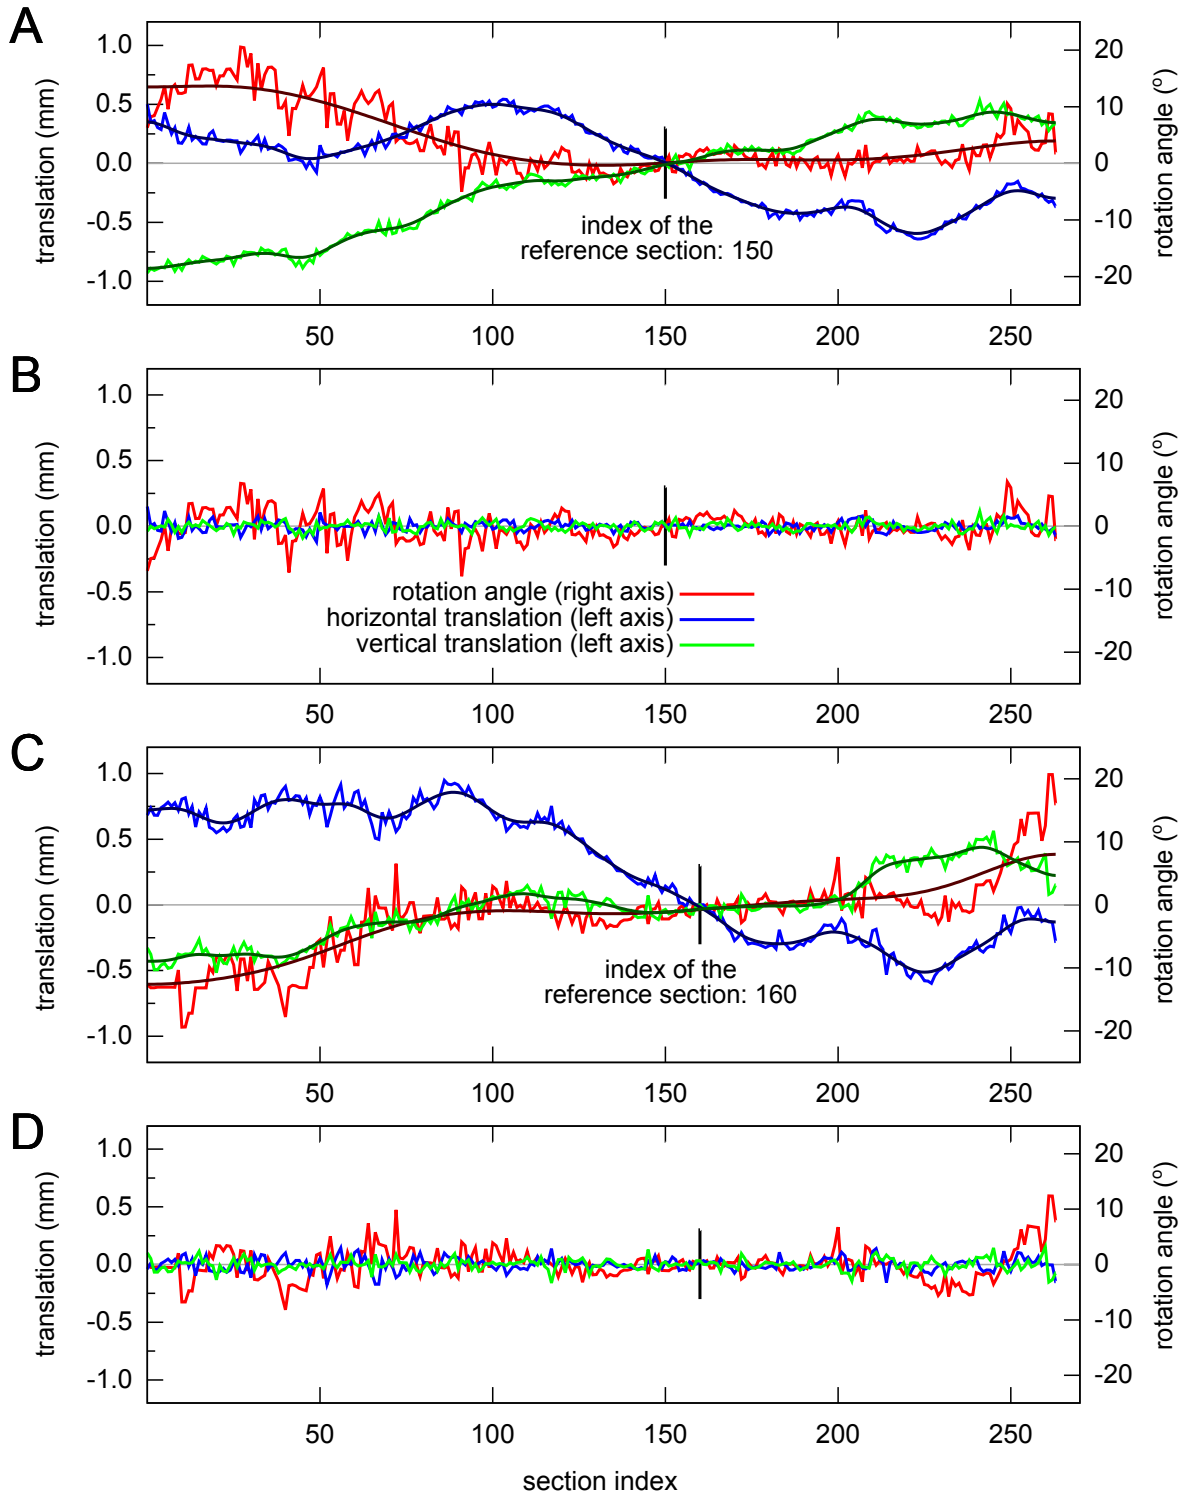

Figure S2: Results of the coarse- and fine-stage tranformations calculated during the rigid reconstruction of the 3D brain images based on series of Nissl- and myelin-stained sections. The abscissas denote indexes of the sections (1-264), the left ordinate axis denotes the translation while the right axis denotes the rotation angle for the given section. The red curves indicate the rotation angle, the blue curves denote the translation in the horizontal direction while the green curves mark translation in the vertical direction. **A)** Alignment of the Nissl-stained sections. Bright colors indicate parameters of the fine-scale transformations. Dark shades of red, green and blue denote parameters of the low-frequency component of the fine-scale transformations parameters. **B)** High-frequency component of the fine-scale transformation used to obtain the rigid reconstruction of the Nissl-stained sections. **C-D)** Anologous results for the sections stained for myelinated fibres.

Detailed description of the deformable reconstruction step

The deformable reconstruction process was split into four stages. The output of one stage constituted the input to the next one. First, highly deformed sections which, if unchanged, would cause reconstruction artefacts, were fixed. They were selected manually and corrected by warping towards the closest undistorted neighbor. Registration parameters were chosen individually depending on the type and magnitude of the distortion. The next step was to reconstruct smooth brain outline. The input data were the sections' outlines warped using transformations computed in the previous step and the summed square distance was used as the image similarity metric. The last step was reconstruction of the interior of the brain volume and was divided into two parts – coarse and fine. While this division is not strict, it emphasizes the necessity of using different sets of parameters to gradually increase the reconstruction precision. As the registration in this stage uses intensity images and is intra-modal, cross-correlation is used as a similarity metric.

Table S1: Parameters for deformable reconstruction of brain volume based on Nissl-stained sections.

Number of iterations	Image type	Sections range	ANTS registration parameters
(–)	images	34 selected (*)	CC(16, 0.5), Gauss(3,1), Iterations: 1000x1000x1000x0x0
5	masks	whole stack	MSQ(-, 0.05), Gauss(1,1), Iterations: 1000x1000x1000x0x0
5	images	whole stack	CC(4, 0.05), Gauss(1,1), Iterations: 1000x1000x1000x0x0
6	images	whole stack	CC(4, 0.01), Gauss(1,1), Iterations: 1000x1000x1000x0x0
2	images	1-80 (**)	CC(4, 0.01), Gauss(1,1), Iterations: 1000x1000x1000x0x0

(–) the initial step is not considered as an iteration; (*) Compensation of highly deformed sections was performed on a manually selected set of slices (see text for explanation); (**) Two more iterations were carried out for section constituting the olfactory bulb to improve the shape of this part of the brain.

Table S2: Parameters for deformable reconstruction of brain volume based on myelin-stained slices.

Number of iterations	Image type	Sections range	ANTS registration parameters
(–)	images	17 selected (*)	CC(16, 0.5), Gauss(3,1); CC(4, 0.25), Gauss(3,1) (**), Iterations: 1000x1000x1000x0x0
8	masks	whole stack	MSQ(-, 0.05), Gauss(1,1), Iterations: 1000x1000x1000x0x0
5	images	whole stack	CC(2, 0.01), Gauss(1,1), Iterations: 1000x1000x1000x0x0
4	images	1-80 (***)	CC(2, 0.01), Gauss(1,1), Iterations: 1000x1000x1000x0x0

(–) the initial step is not considered as an iteration; (*) Compensation of highly deformed slices was performed on a manually selected set of slices (see text for explanation); (**) All sets of different parameters used in this stage are presented as different slices were corrected using different parameters; (***) Two more iterations were carried out for slices constituting the olfactory bulb to improve the shape of this part of the brain.

Table S3: Summary of the parameters used during deformable coregistration of the histological volumes towards the MR image.

step no.	w_{CC}	w_{MSQ}	w_{PSE}	fixed / moving image resolution (μm)	ANTS registration parameters
1	0	1	1.0	200	CC(5), SyN(0.35), Gauss(0,0), Iterations: 1000x1000
2-3	1	0	0.5	200	CC(5), SyN(0.25), Gauss(0,0), Iterations: 1000
4-6	1	0	0.5	100	CC(5), SyN(0.25), Gauss(0,0.1), Iterations: 1000
7-8	1	0	0.5	75	CC(5), SyN(0.25), Gauss(0,0.75), Iterations: 1000
9-10	1	0	0.5	50	CC(5), SyN(0.25), Gauss(0,0.05), Iterations: 1000

w_{CC}: weight of the cross-correlation metric; w_{MSQ}: weight of the summed square distances metric; w_{PSE}: weight of the point set estimation metric.

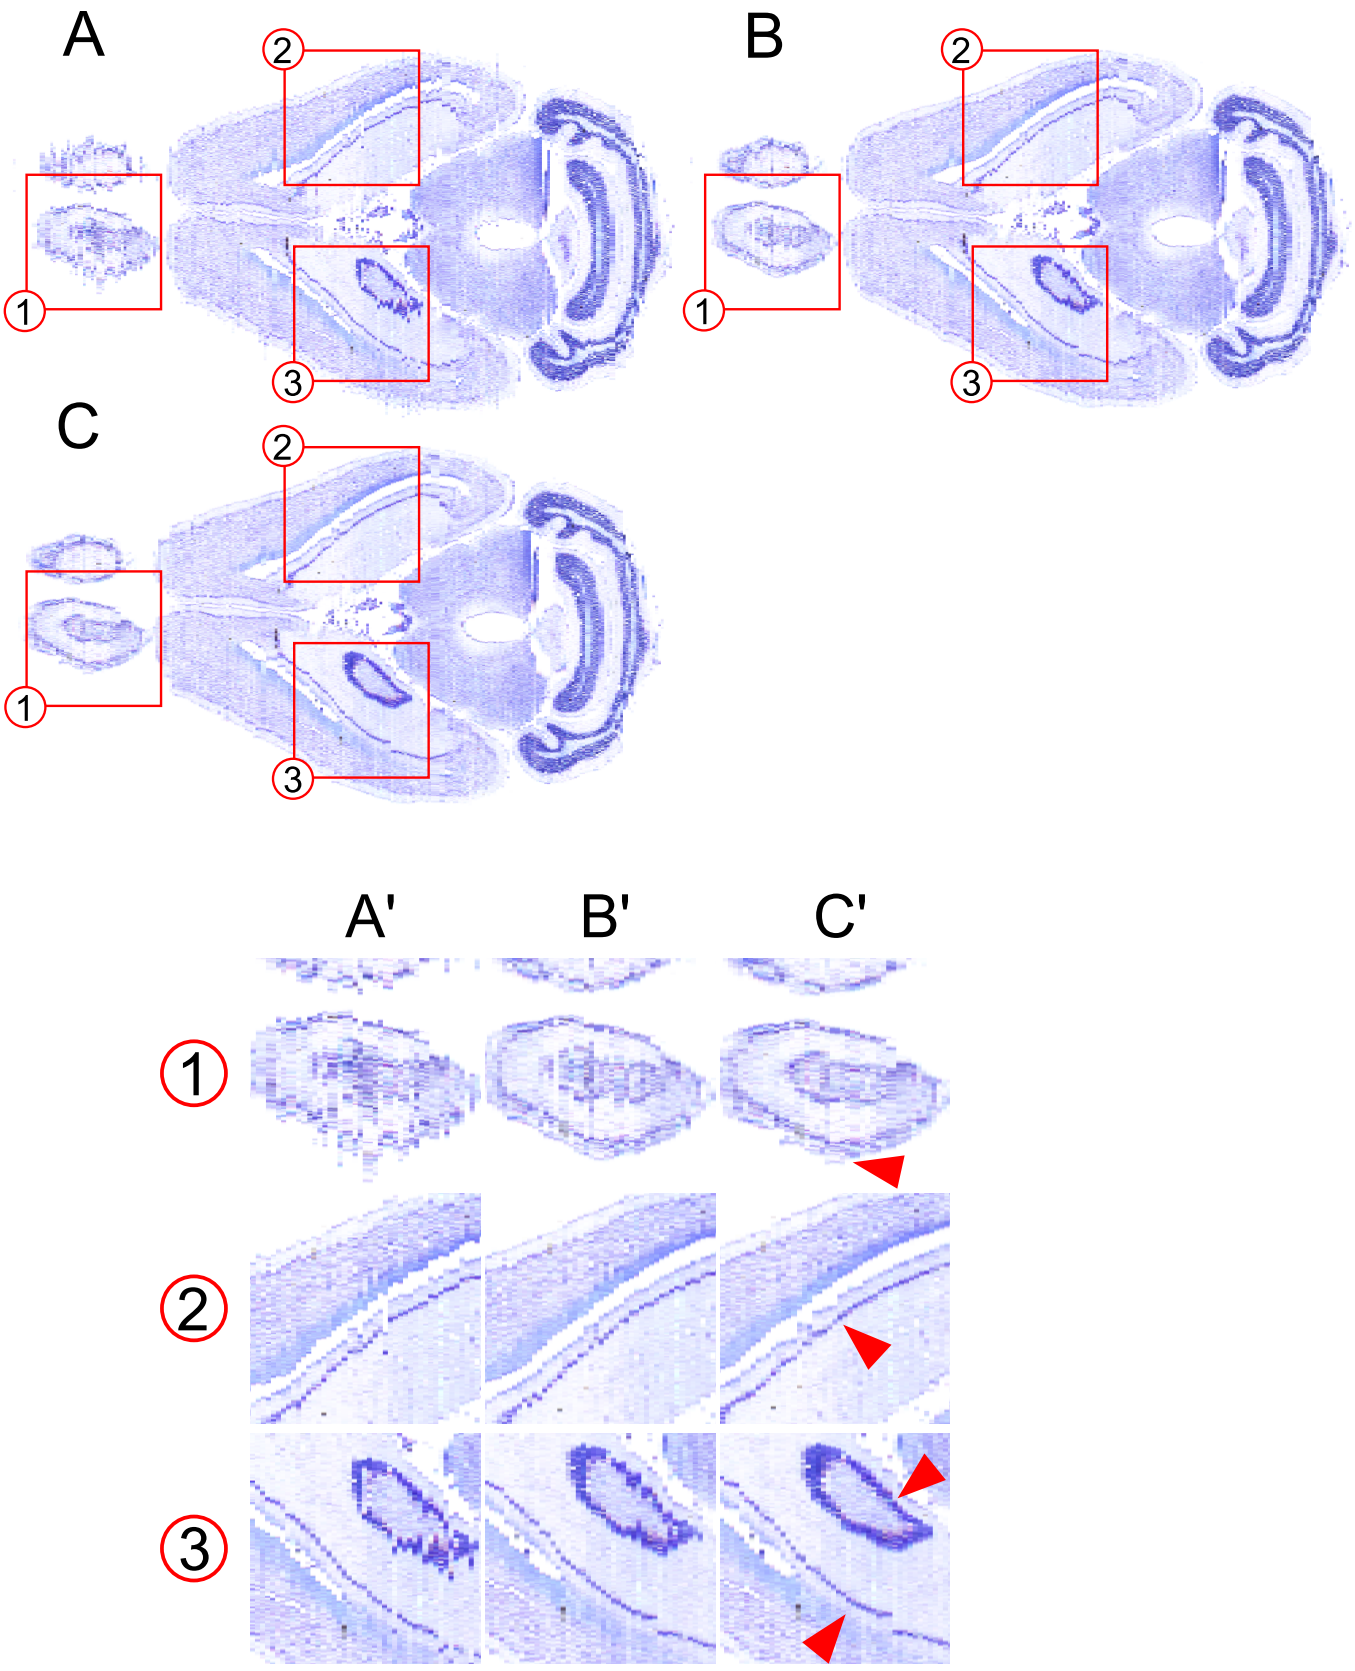

Figure S3: Consecutive steps of the deformable refinement of the 3D brain image based on images of serial coronal sections stained with the Nissl method; Horizontal cross-sections. A) Input rigid reconstruction; B) Reconstruction after alignment of the sections' outlines; C) Final deformable reconstruction. Rows ① to ③ depict fragments denoted with red rectangles on panels A-C. Red trianges indicate fragments of the reconstruction which have improved the most significantly in comparison with the input affine reconstruction.

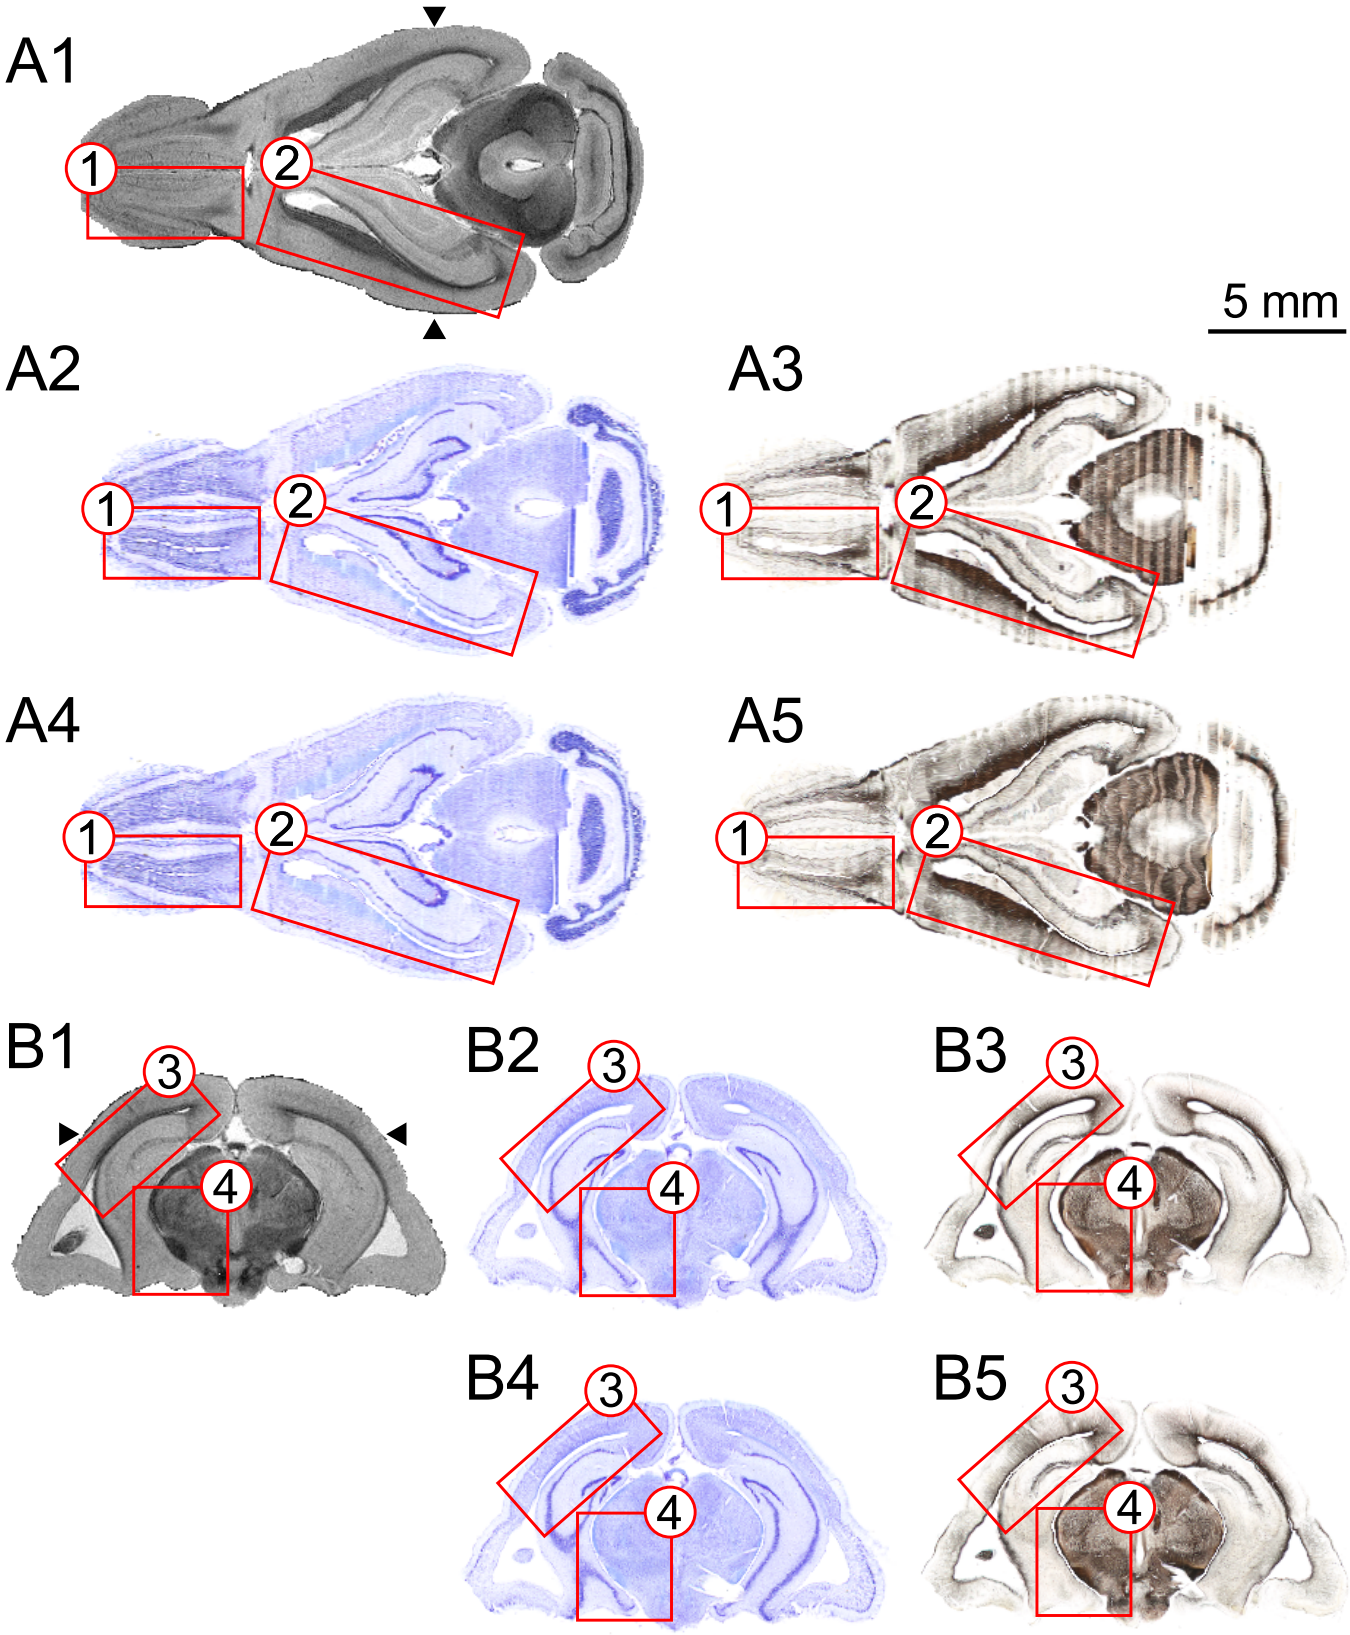

Figure S4: Comparison of the results of the coregistration of the 3D reconstructions based on the Nissl- and myelin-stained sections with the reference MR image (A1, B1) after the affine coregistration (A2, A3, B2, B3) and after the deformable coregistration step (A4, A5, B4, B5). Horizontal (A1-A5) and coronal cuts (B1-B5). After only the affine coregistration step, the distortions specific to the staining technique are noticeable e.g. tissue shrinkage next to ventricles (red rectangles ② and ③). After the deformable reconstruction step these distortions have been significantly mitigated (compare e.g. A3-② vs. A5-② or B3-③ vs. B5-③).

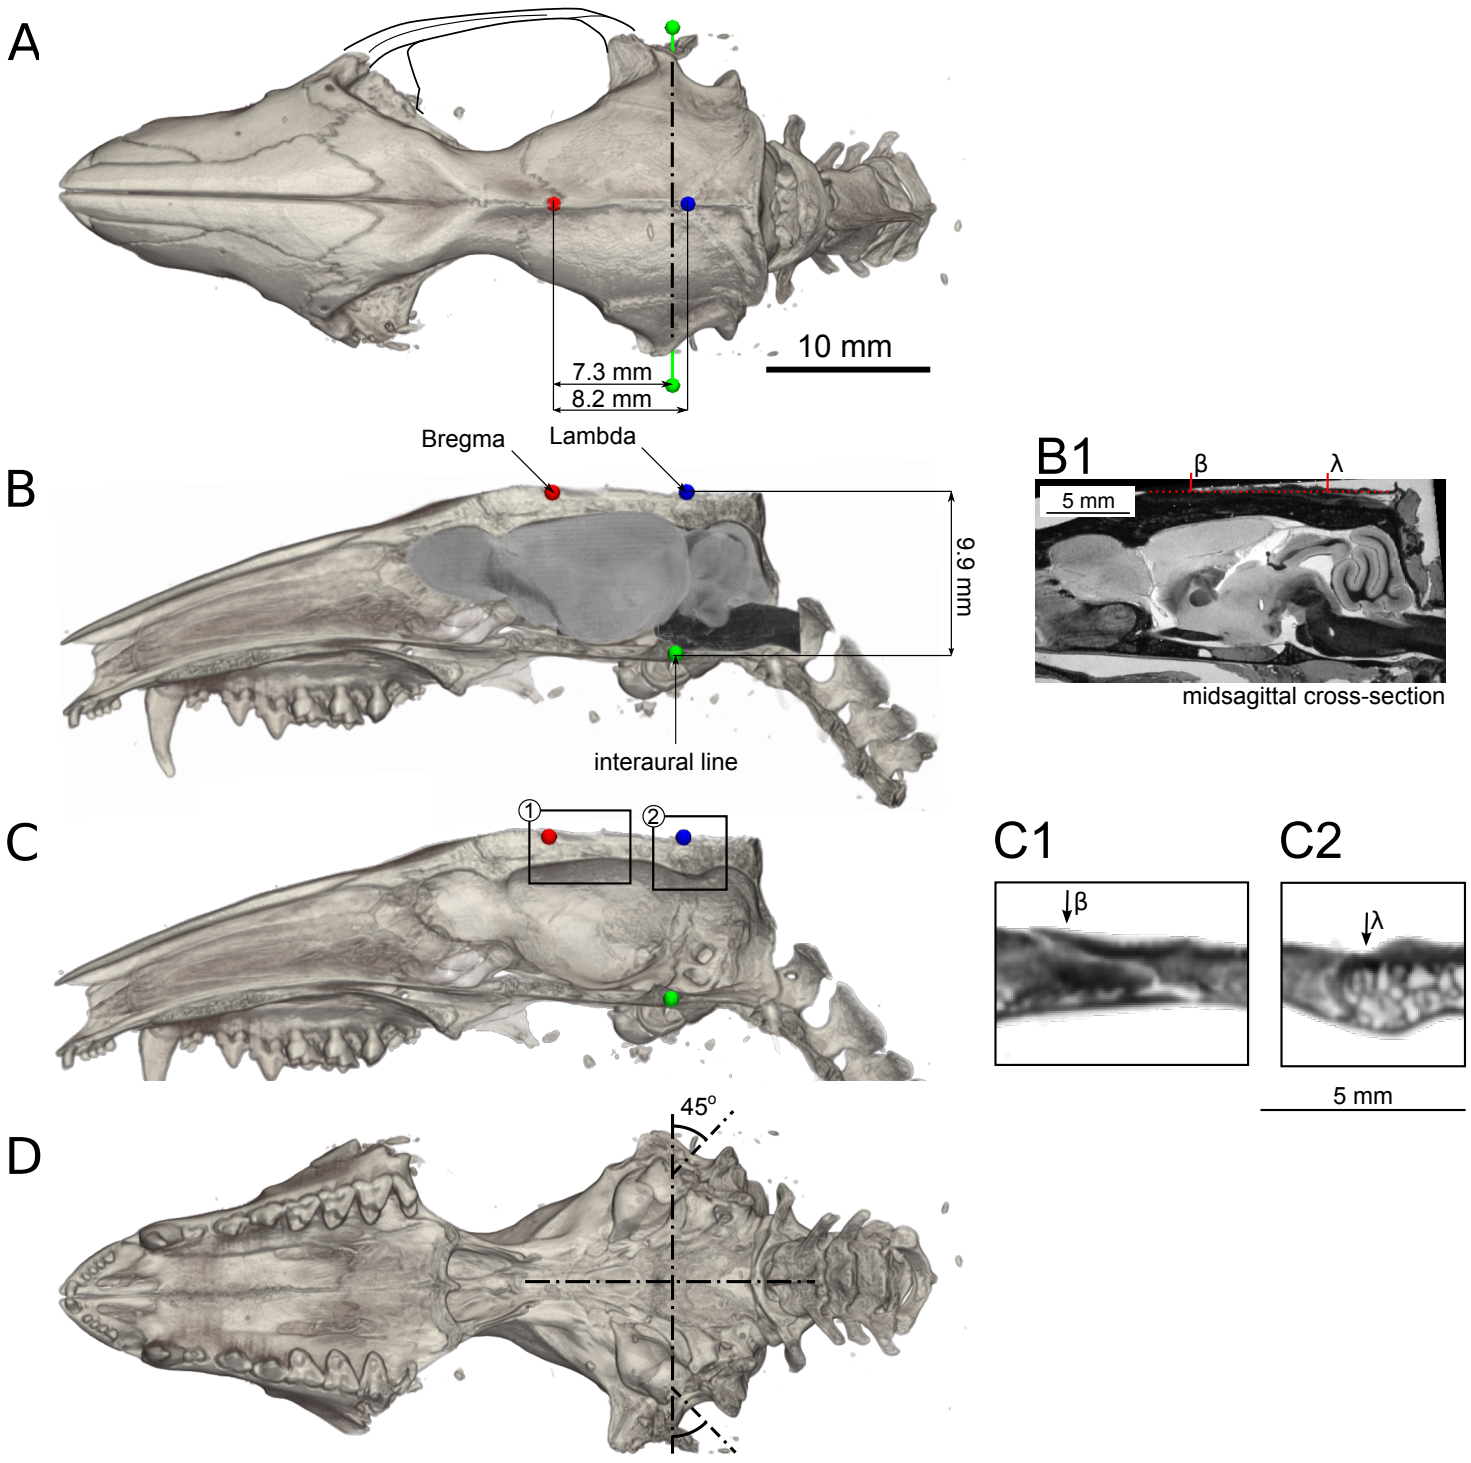

Figure S5: Extended ilustration of the structure of the opossum skull and the landmarks used to establish the stereotaxic coordinate system. A) Horizontal projection; the right zygomatic arch, trimmed during preparative procedures, was drawn manually; B) sagittal projection; the skull was digitally cut along the midsagittal plane and the MR image aligned to the braincase is shown. B1) Midsagittal cross-section through the MR image, the arrows indicate the location of the cranial landmarks, bregma (β) and lambda (λ). The dotted line indicates the level of both landmarks. C) Midsagittal cross-section through the skull whithout the MR image overlay. The braincase is clearly visible in detail. Rectangles ① and ② highlight the neighborhood of the bregma and lambda points magnified on panels C1 and C2, respectively. D) Ventral projection; the entry to the ear canals is angled at approx. 45 deg.

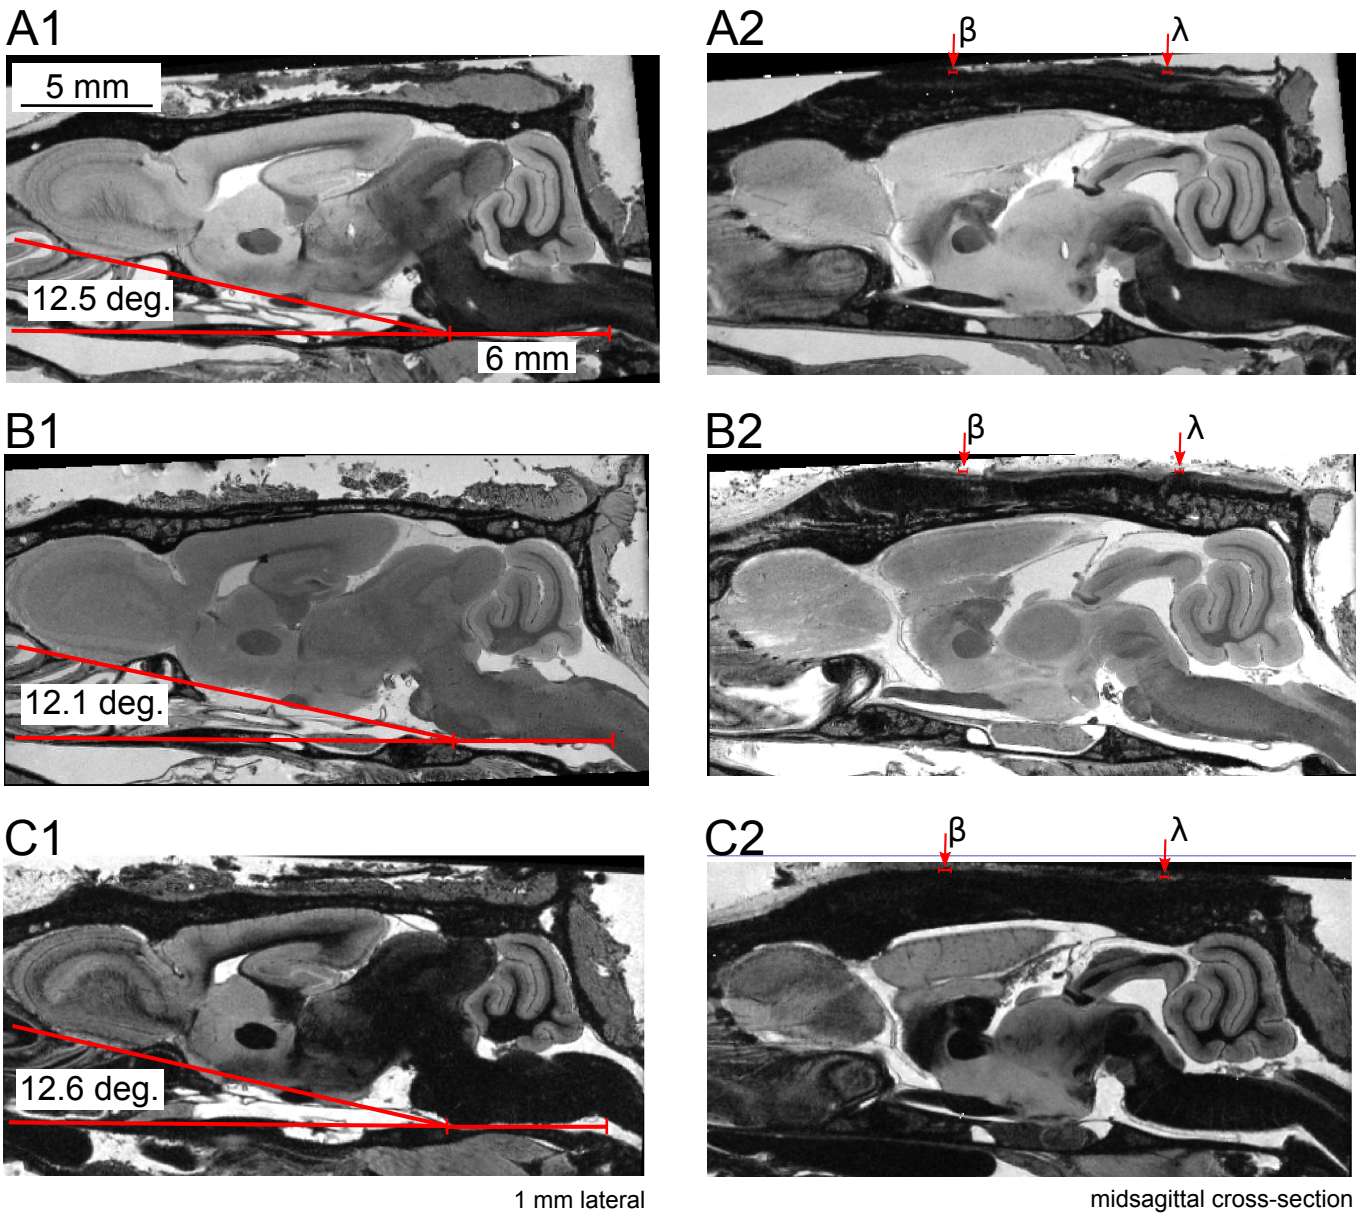

Figure S6: The method for establishing the stereotaxic orientation illustrated with three diferent specimen of one year male opossum imaged using the same MR protocol. The brain is positioned so that the ventral surfaces of the pons and the brainstem are oriented horizontally (the horizontal red lines in the left column). In this orientation, the brain is lifted rostrally by 11-13° and the bregma and lambda are also aligned horizontally. The coronal sectioning plane defined in this way is relatively easy to determine in a live animal for the purpose of stereotaxic interventions. A) The brain of an animal from which the Nissl- and myelin-stained sections were obtained. B and C) Additional specimen not described in the article. A1-C1) Parasagittal cross sections, 1 mm lateral from the midsagittal plane: at this level the flat orientation of the brainstem is clearly visible. A2-C2) Cross-sections through the midsagittal plane. The large sagittal crest is clearly visible dorsal to the brain. The arrows indicate the location of the cranial landmarks, bregma (β) and lambda (λ). The small red bars near the landmarks illustrate the uncertainity of finding these points using only the MR images. Out of the three examples presented in this figure, only in the case B the landmarks can be located unambigously. For comparison, see also Fig. S5, panels C, C1, and C2.

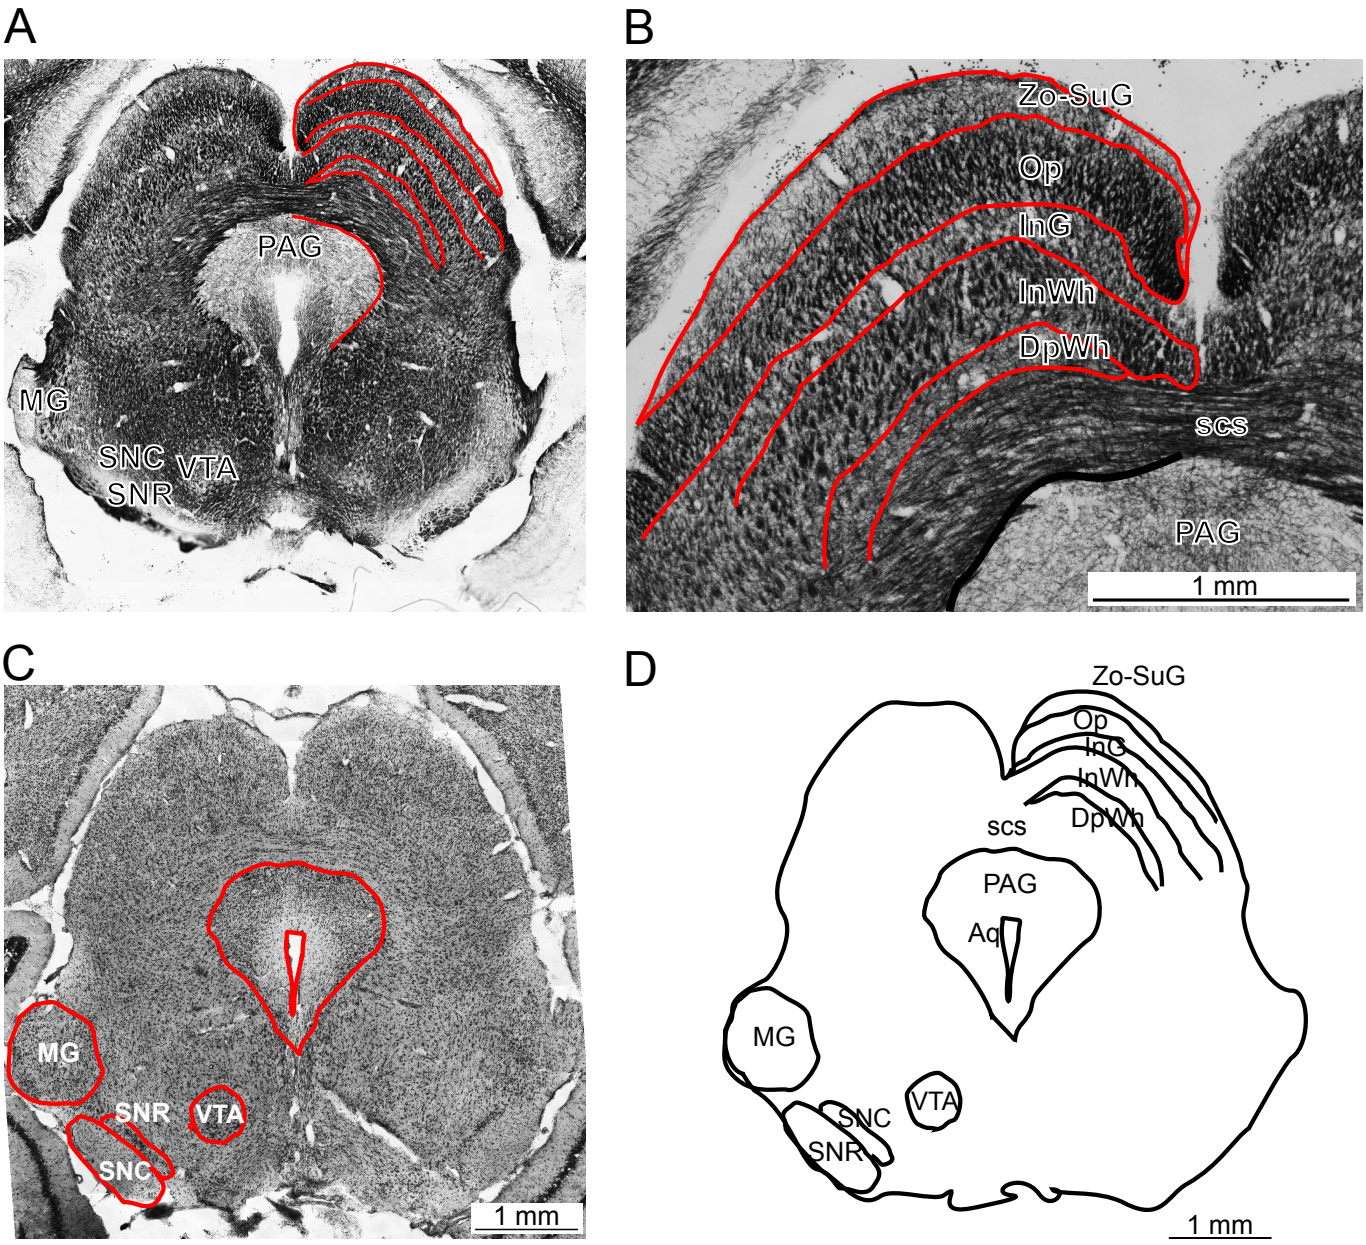

Figure S7: Images of coronal transections through the midbrain on myelin- (A, B) and Nissl-stained (C) sections under a microscope. The same myelin-stained section in low (A) and high (B) magnification. Layers of the superior colliculus are best distinguished by differential intensity of myelin staining.

Interpenduncular nucleus (IP) 0.7
Lateral lemniscus (LL) 4.9
Median raphe nuclei (MR) 0.6
Olivary nuclei (O) 2.0
Pontine nuclei (Pn) 2.1
Superior cerebellar peduncle (SCP) 1.3
Ventral tegmental nucleus (VTg) 0.1
Longitudinal fasciculus of the pons (lfp) 0.2
Motor root of trigeminal nerve (m5) 0.5
Middle cerebellar peduncle (mcp) 2.0
Pons - unsegmented (P-U) 24.9
Medulla oblongata (MY) 68.6
Cochlear nucleus (CN) 3.9
Vestibular nucleus (Ve) 4.5
Facial nerve (7n) 0.5
Facial nucleus (7N) 0.6
Hypoglossal nucleus and central cervical nucleus (12N) 1.0
Cuneate nucleus (Cu) 2.9
Gracile nucleus (Gr) 1.1
Inferior olive (IO) 0.6
Area postrema (AP) 0.1
Nuclei of the solitary tract (Sol) 1.0
Paratrigeminal nucleus (Pa5) 0.1
Spinal trigeminal nucleus (Sp5) 7.1
Pyramidal tract (py) 2.0
Medial lemniscus (ml) 0.4
Dorsal spinocerebellar tract (dsc) 2.4
Ventral spinocerebellar tract (vsc) 3.9
Medulla oblongata - unsegmented (MY - U) 36.4
Fiber tracts (FT) 35.9
Cingulum (cg) 0.3
Fornix (f) 1.0
Optic chiasm (och) 1.1
Optic tract (opt) 5.4
Stria terminalis (st) 1.3
Mammillary peduncle (mp) 0.2
Mammillothalamic tract (mt) 0.4
Retromammillary decussation (rmx) 0.0
Cerebral peduncle (cp) 2.8
Fasciculus retroflexus (fr) 0.8
Mesencephalic trigeminal tract (me5) 0.6
Inferior cerebellar peduncle (icp) 1.5
Tectospinal tract (ts) 8.7
Sensory root of trigeminal nerve (s5) 11.6
Ventricles (V) 24.6
Lateral ventricle (LV) 19.2
Interventricular foramen (IVF) 0.3
3rd ventricle (3V) 1.2
Cerebral aqueduct (Aq) 0.9
4th ventricle (4V) 3.0
