Supplementary Figure 10 | Photoresponse enhancement in Al$_2$O$_3$ sandwiched MoS$_2$ 3D photodetector. a, Schematic illustrations of devices in cross-sectional view (left) displaying trapped water (H$_2$O) and oxygen (O$_2$) molecules without Al$_2$O$_3$ and the elimination of such traps with insertion of Al$_2$O$_3$ at the MoS$_2$ interfaces. The traps deplete the carriers in MoS$_2$ (right, top); insertion of Al$_2$O$_3$ reduces such effects. **b**, Cross-sectional transmission electron

11

microscope image of a $Al_2O_3/MoS_2/Al_2O_3$ sandwich structure, highlighting the physical nature of the Al_2O_3/MoS_2 interfaces. **c,** The photoresponses of a photoresistor without encapsulation, with top Al_2O_3 encapsulation, and with top and bottom (sandwich) Al_2O_3 encapsulation. **d,** The rise and decay time clearly reveal a significant increase in response speed (20 times) with the addition of high-k dielectric encapsulation, as compared to the unencapsulated case. **e,** Optical photograph of 3D photodetector with a sandwiched structure and **f,** corresponding photoimaging results. The high-k Al_2O_3 layer provides a clean, conformal contact, and imparts low surface roughness to the MoS_2 interface, thereby reducing the interface traps. Additionally, the large dielectric mismatch between Al_2O_3 and MoS_2 suppresses Coulombic impurities in MoS_2, further decreasing the carrier trapping during transport. The effects facilitate fast carrier transport upon illumination, thus increasing the response speed.
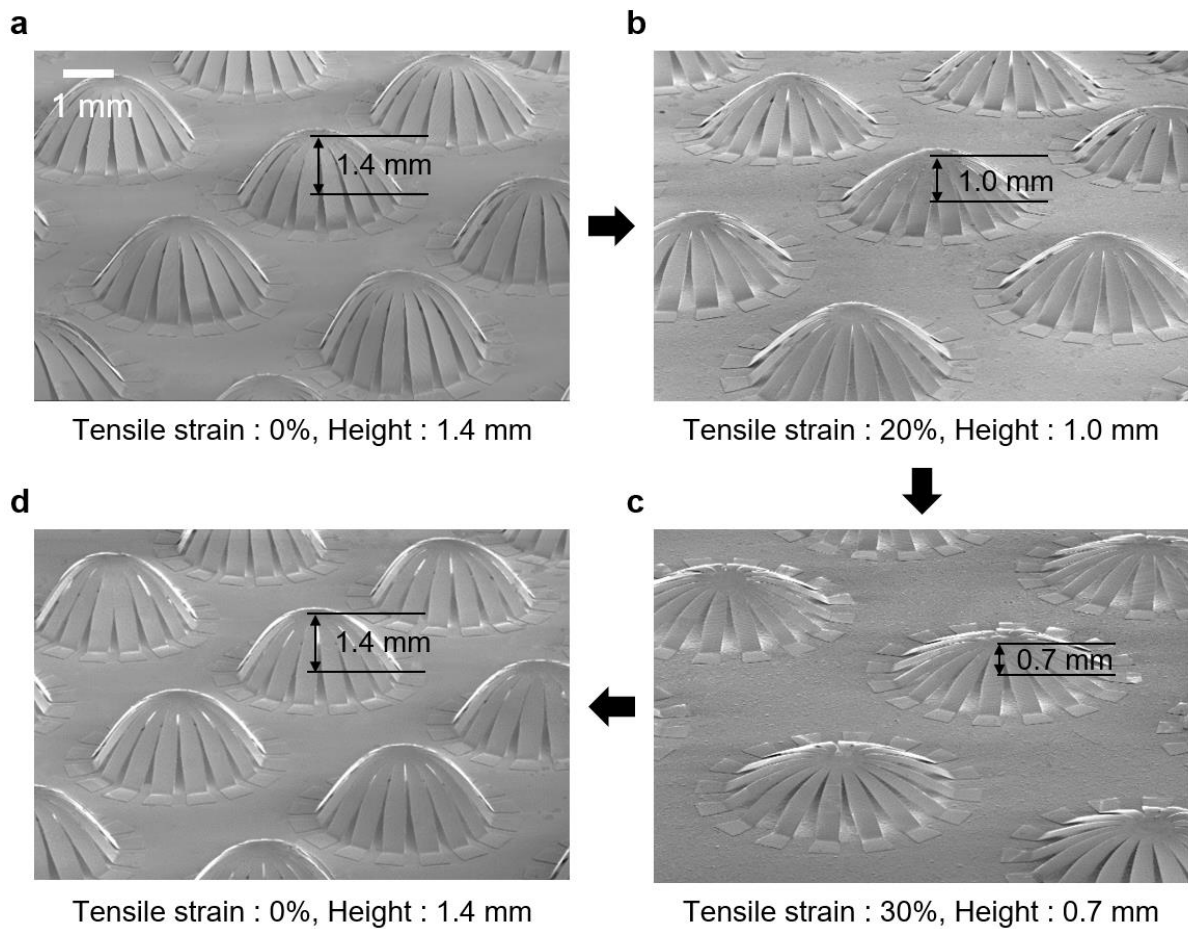

Supplementary Figure 11 | Stability test in ambient environment. The dark current and photoresponse(Standard deviation) remain unchanged over > 3 months (the duration of the test), indicating excellent environmental stability and consequent potential for use in practical applications. The stable operation follows partly from the chemically inert nature of the constituent 2D materials; graphene and MoS_2.
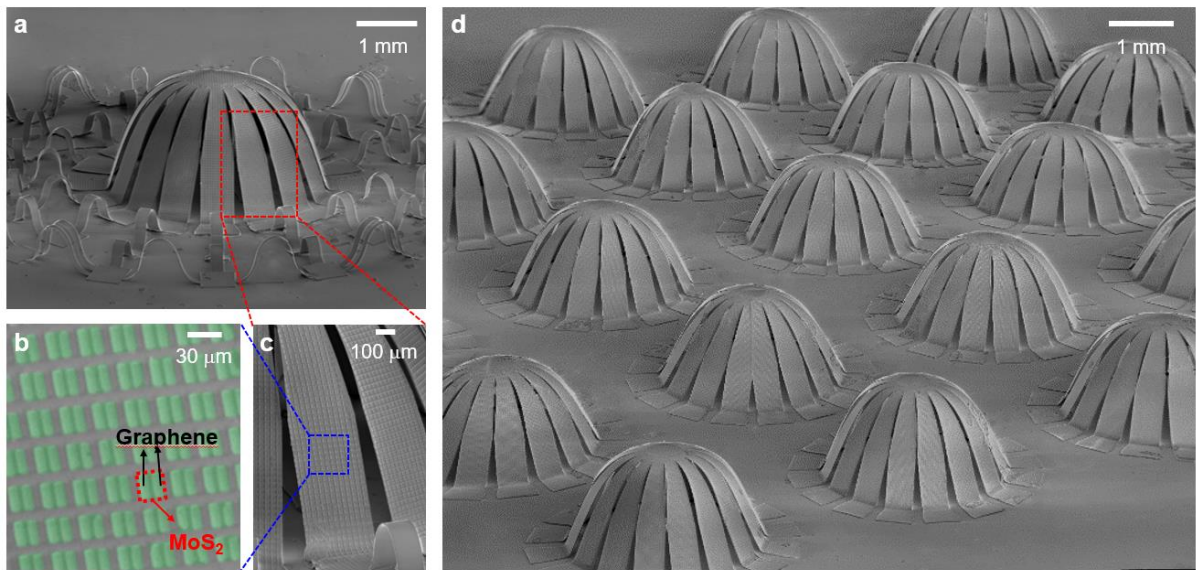

Supplementary Figure 12 | SEM image of scalable, parallel formation of an array of 3D photodetection systems. Each incorporates 10,000 individual photoresistor units (16 arms, each arm accommodating ~6,000 photoresistors) on its surface (**a**, **b** and **c**). These densely packed devices follow from a single assembly step, from a collection of 2D precursors fabricated in parallel using planar processing techniques. The scalability in resolution and the parallelism of the manufacturing approaches are consistent with use in practical applications. **d**, SEM image of a 5x5 array of such 3D structures.
Supplementary Figure 13 | SEM mapping under bent states. a, SEM image of an array of 3D photodetector systems was recorded in a bent configuration (bending radius 1 cm) **b**, Magnified view of the center part in a bent configuration. The absence of any evidence of delamination or cracking indicates its excellent mechanical endurance during bending.

Supplementary Figure 14 | SEM mapping under in-plane stretching. SEM images of an array of 3D photodetector systems were taken under different in-plane biaxial stretching states (a-d). Each 3D structure in the 5×5 array stretches uniformly in the lateral direction through reductions in the height. The systems return to their original dimensions after release (same height before and after releasing the stretching; (**a** and **d**). No cracks or delaminations appear during repeated stretching, thereby confirming the excellent mechanical robustness of 3D pop-up hemispherical photodetectors.
Supplementary Figure 15 | Estimation of transparency of different regions of 3D photodetector. Black line indicates the SU-8 film, red line indicates graphene electrode on SU-8 and blue line indicates MoS$_2$/Graphene/SU-8 structure.
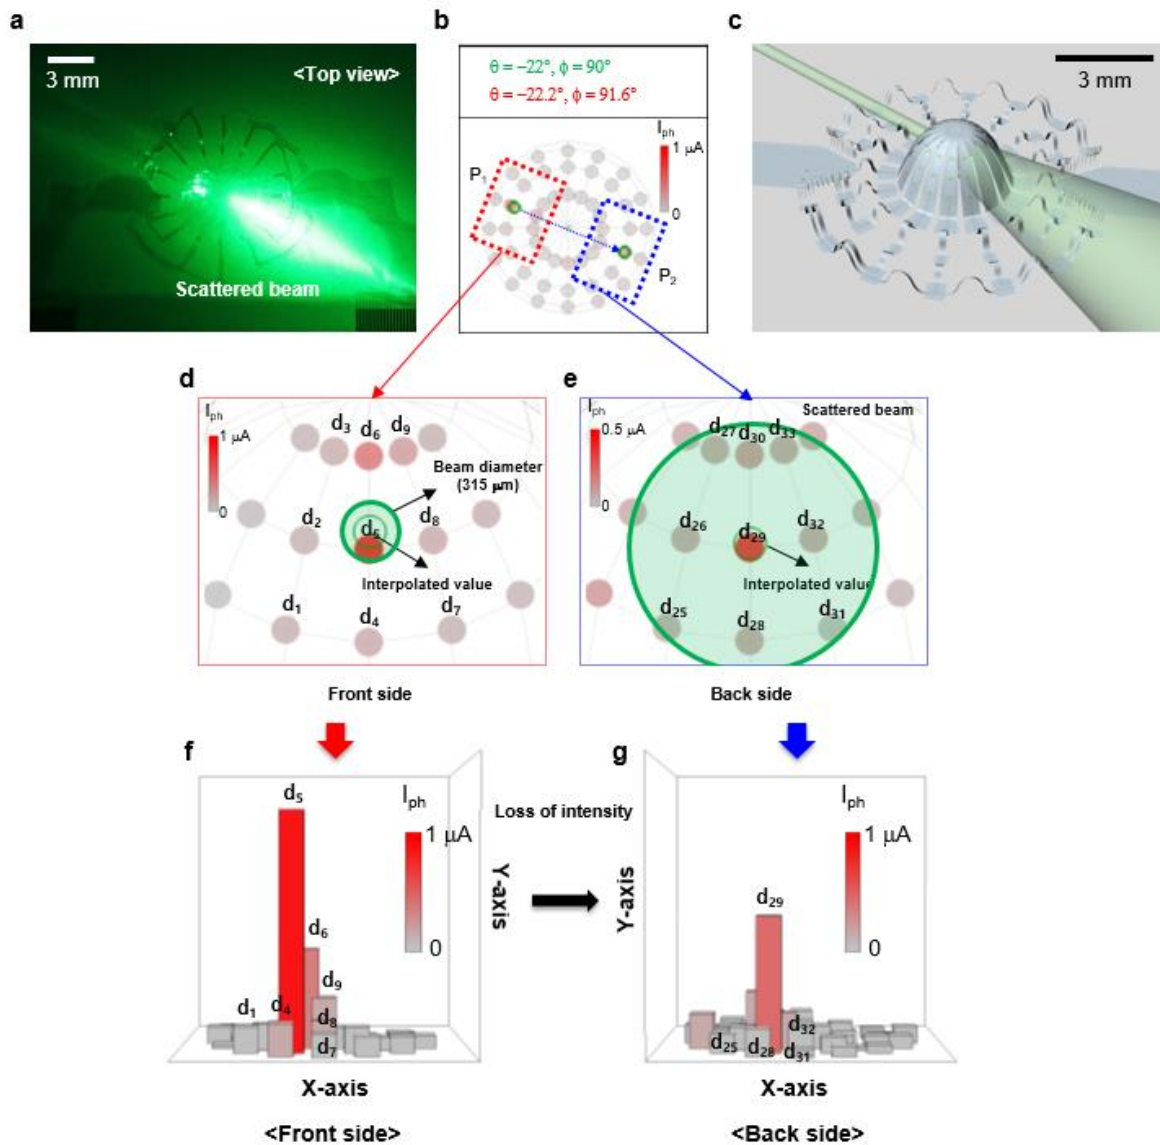

Supplementary Figure 16 | The role of scattered laser light in identifying the position and direction of the incident laser beam. a, Optical photograph, **b**, photoimaging results, and **c**, schematic illustrations of the intentional condition for maximum scattered light. Scattering affects most strongly the photoresistors near the location where the laser beam enters and exits the 3D surface. This feature is confirmed by the recorded photoresponse (**d** and **e**) and its intensity distribution (**f** and **g**) from nearest photoresistors that are not directly illuminated by the laser beam. Among 9 devices which were considered to identify the position and direction of the laser beam, only d_5 at P_1 and d_{29} at P_2 respond to the incident light while rest of the devices respond only due to scattered light. The photoresponse at P_2 (**g**) decreases as compared to P_1 (**f**) due to the loss of light intensity in passing through the 3D shape. These data highlight the importance of transparency.

Supplementary Figure 17 | Angle measurement of incident laser on 3D photodetector. Adjustment of the laser incident angle a, with the range from -45° to 45° for θ and 90° for ϕ and **b**, with the range of incident angle from 90° to 67.5° for ϕ and 0° for θ to 3D photodetector with a protractor.

Supplementary Figure 18 | Photocurrent maps of 3D hemispherical photodetector.
All the MoS$_2$ photodetectors expressed by bar graphs corresponding to the cases in Figure 4.
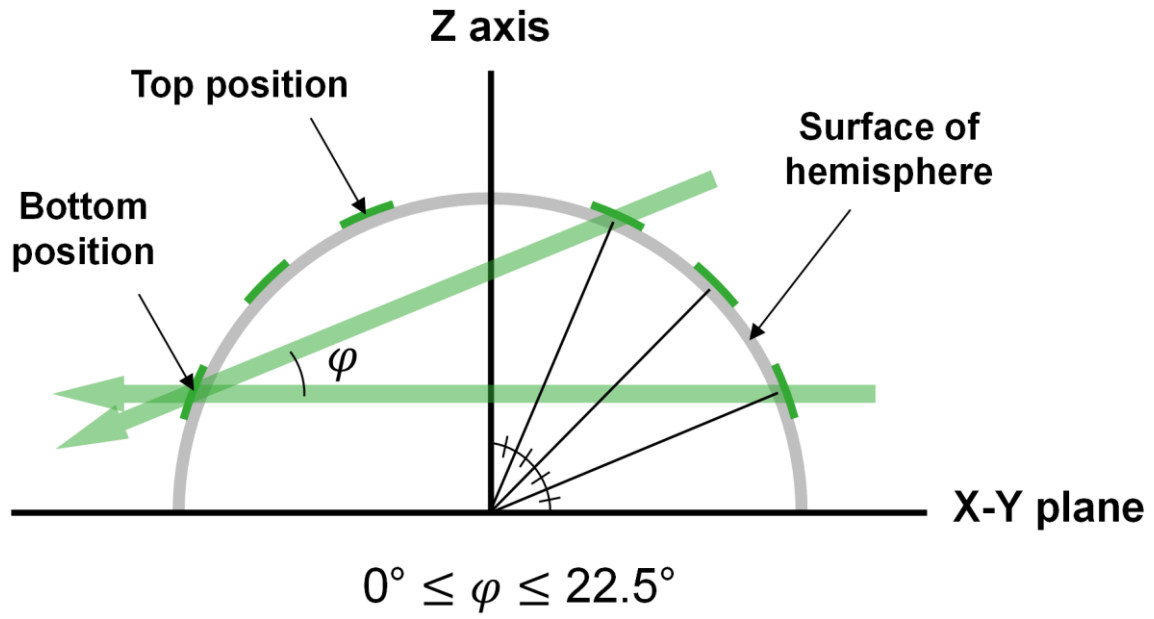

Supplementary Figure 19 | Schematic illustration of incident laser on 3D photodetector (low density array). The detectable range of φ is from 0° to 22.5°.
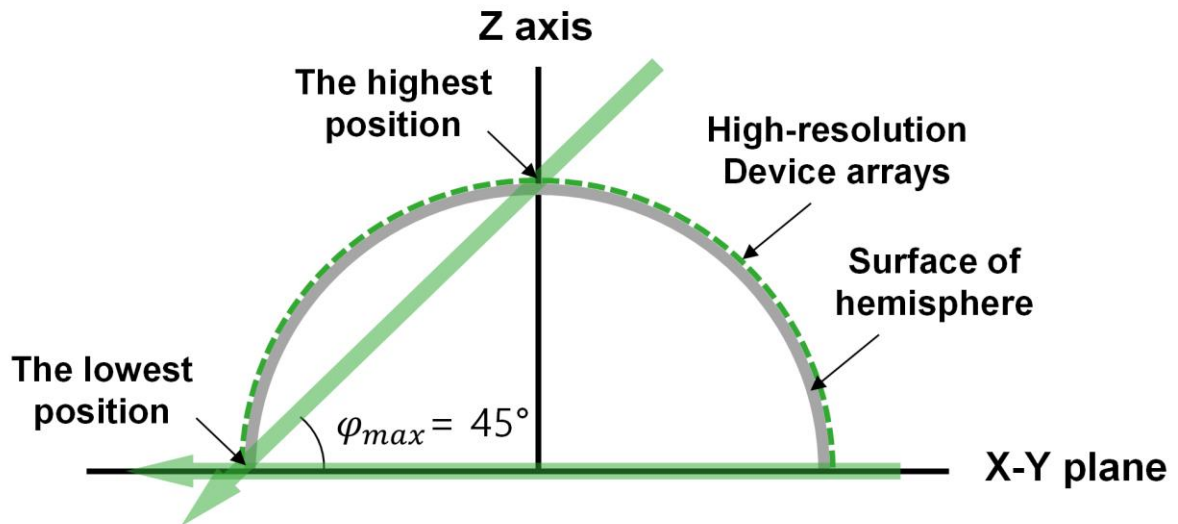

Supplementary Figure 20 | Schematic illustration of incident laser on 3D photodetector (high density array). The maximum detectable azimuth angle (φ_{max}) is 45°.
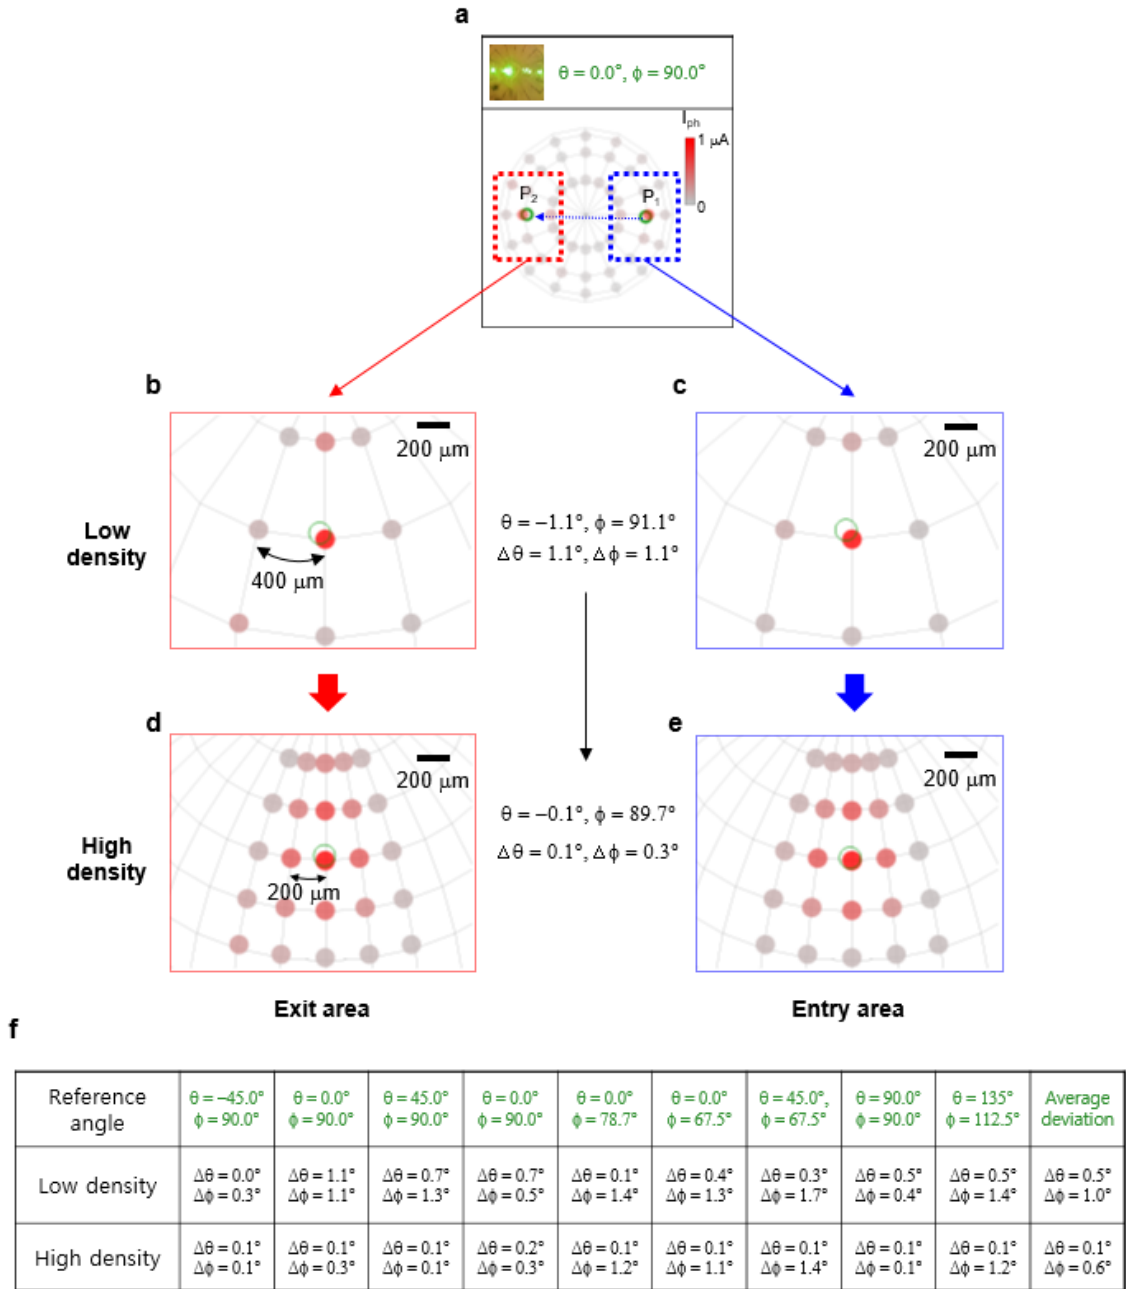

Supplementary Figure 21 | Results that highlight the effects of distances among photoresistors in a 3D imaging system. A particular incident condition of laser beam is considered (**a**) and measurements for identifying the positions are performed for a low density array (**b** and **c**) and for a high density array (distances between photoresistors are half of those in the low density array) (**d** and **e**). The measurement results are tabulated in the form of deviation between measured and actual position of the beam. The measured deviation is less for the high density array as compared to the low density array of devices, indicating that the accuracy in identifying the position of the laser beam increases with decreasing the distances among fabricated devices.

Supplementary Figure 22 | The effect of beam size on the accuracy of identifying the position of illumination. The incident point of laser beam on 3D hemispherical structure was identified (in the form of deviation, **a**) by changing the beam diameter (**b** and **c**) without changing the positions of the laser and 3D photodetector. The obtained photoresponses at P_1 and P_2 (**d**) for three different beam diameters (**b** and **c**) were used to calculate the deviation (**a**) between measured incident and actual position. The measured deviation was larger for larger beam diameters, indicating that the accuracy decreases with increasing laser spot size.

24

Measuring frequency : 64 Hz	160 Hz	480 Hz	1080 Hz

Supplementary Figure 23 | High frequency photoimaging capabilities with a 3D hemispherical photodetector. The positions of incident laser beam at entry (P_1) and exit (P_2) regions were identified (**b**) through the measured photoresponses (**c**) with increasing frequency. Although the deviation between measured position and actual one (**a**) slightly increases with frequencies, the system can identify the positions of the laser beam well into the kHz range (**b**, right).
Supplementary Figure 24 | Raman Mapping of MoS$_2$. The raman spectrum of the used mono-layer MoS$_2$ grown by CVD method. Inset shows its room temperature photoluminescence spectrum.
Supplementary Figure 25 | Raman mapping of graphene. The raman spectrum of double-layer graphene was recorded.
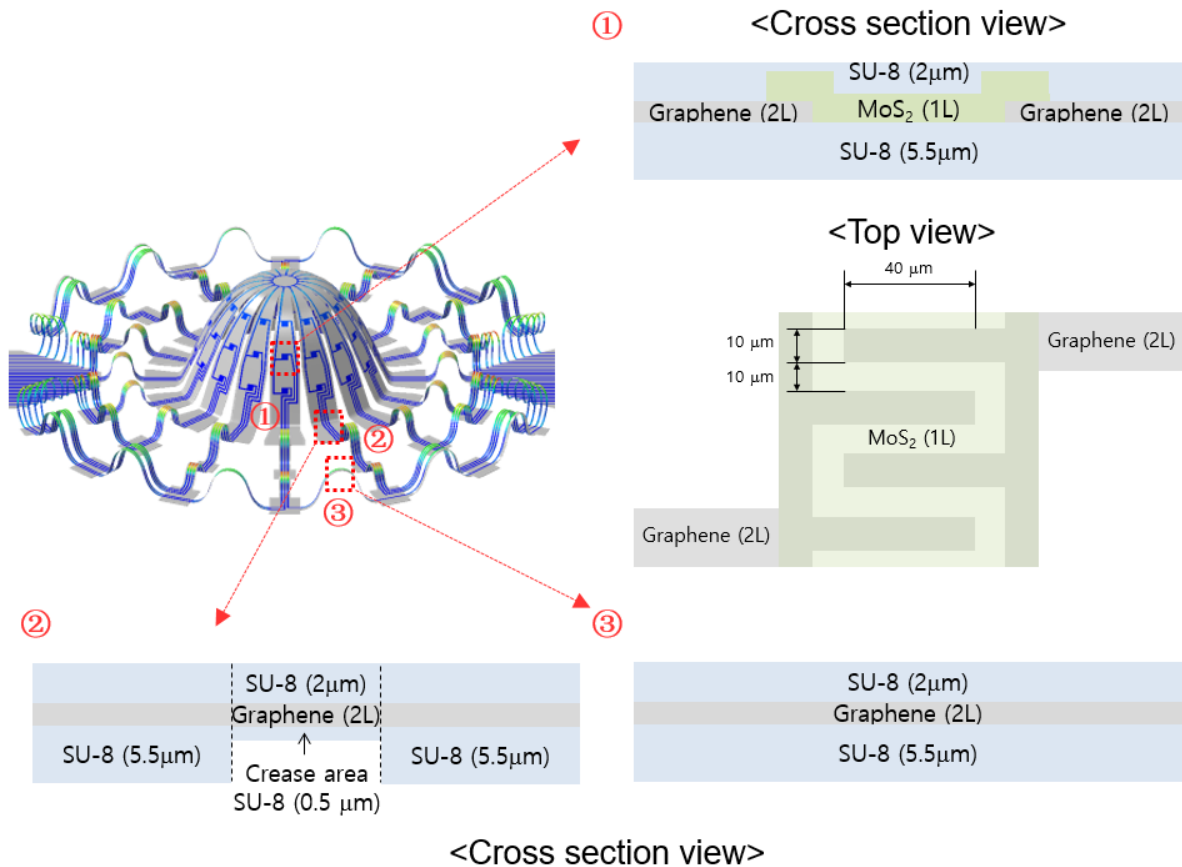

Supplementary Figure 26 | Detailed information on multilayer structures used in different regions of a 3D hemispherical photodetector structure: ①, The active part (cross section and top views) of the 3D structure includes monolayer MoS_2 as a photoactive layer with interdigitated bilayer graphene electrodes, all encapsulated between layers of SU-8. The channel length and width are 10 µm and 40 µm, respectively. ② and ③, Bilayer graphene passivated with SU-8 layers serve as interconnects and connections to the electrodes; the crease regions use thinner bottom SU-8 (②) while the other regions have relatively thicker bottom SU-8 (③).
Supplementary Figure 27 | Band alignments at the graphene/MoS$_2$ interfaces during the photo-operation of a MoS$_2$ based resistive photodetector. Charge carriers, electrons (blue) and holes (red), are generated upon illumination and they are collected with the application of bias voltages, resulting in photocurrent. The solid lines indicate the valence band (E$_V$) and conduction band (E$_C$), while the dashed line represents the Fermi level. For V$_{DS} > 0$, the holes move toward the valence band (red arrow) and electrons move toward the conduction band (blue arrow).
