## Real-time DNA barcoding in a rainforest using nanopore sequencing: opportunities for rapid biodiversity assessments and local capacity building

--Manuscript Draft--

<b>Manuscript Number:</b>	GIGA-D-17-00345	
<b>Full Title:</b>	Real-time DNA barcoding in a rainforest using nanopore sequencing: opportunities for rapid biodiversity assessments and local capacity building	
<b>Article Type:</b>	Research	
<b>Funding Information:</b>	National Geographic Society (W412-15)	Mr Aaron Pomerantz
<b>Abstract:</b>	<p><b>Background</b> Advancements in portable scientific instruments provide promising avenues to expedite field work in order to understand the diverse array of organisms that inhabit our planet. Here we tested the feasibility for in situ molecular analyses of endemic fauna using a portable laboratory fitting within a single backpack, in one of the world's most imperiled biodiversity hotspots: the Ecuadorian Chocó rainforest. We utilized portable equipment, including the MinION nanopore sequencer (Oxford Nanopore Technologies) and the miniPCR (miniPCR), to perform DNA extraction, PCR amplification and real-time DNA barcoding of reptile specimens in the field.</p> <p><b>Findings</b> We demonstrate that nanopore sequencing can be implemented in a remote tropical forest to quickly and accurately identify species using DNA barcoding, as we generated consensus sequences for species resolution with an accuracy of &gt;99% in less than 24 hours after collecting specimens. The flexibility of our mobile laboratory further allowed us to generate sequence information at Universidad Tecnológica Indoamérica in Quito for recently collected rare, endangered, and undescribed specimens. This includes the recently re-discovered Jambato toad, which was thought to be extinct for 28 years. Sequences generated on the MinION required as little as 30 reads to achieve high accuracy relative to Sanger sequencing and with further multiplexing of samples, nanopore sequencing can become a cost-effective approach for rapid and portable DNA barcoding.</p> <p><b>Conclusions</b> Overall, we establish how mobile laboratories and nanopore sequencing can help to accelerate species identification in remote areas to aid in conservation efforts and be applied to research facilities in developing countries. This opens up possibilities for biodiversity research by promoting local research capacity building, teaching laymen and students about the environment, tackling wildlife crime or by promoting conservation via research focused eco-tourism.</p>

<b>Opposed Reviewers:</b>	<p>Joe Parker</p> <p>Parker et al. have recently performed genome-skimming on plants with the nanopore sequencer, and we feel they are biased in thinking our study is similar to theirs. We believe our study presented here is significantly different than their approach, but feel their analysis as a reviewer would be prejudiced.</p>
<b>Additional Information:</b>	
<b>Question</b>	<b>Response</b>
Are you submitting this manuscript to a special series or article collection?	No
<p><b>Experimental design and statistics</b></p> <p>Full details of the experimental design and statistical methods used should be given in the Methods section, as detailed in our <a href="#">Minimum Standards Reporting Checklist</a>. Information essential to interpreting the data presented should be made available in the figure legends.</p> <p>Have you included all the information requested in your manuscript?</p>	Yes
<p><b>Resources</b></p> <p>A description of all resources used, including antibodies, cell lines, animals and software tools, with enough information to allow them to be uniquely identified, should be included in the Methods section. Authors are strongly encouraged to cite <a href="#">Research Resource Identifiers</a> (RRIDs) for antibodies, model organisms and tools, where possible.</p> <p>Have you included the information requested as detailed in our <a href="#">Minimum Standards Reporting Checklist</a>?</p>	Yes
<p><b>Availability of data and materials</b></p> <p>All datasets and code on which the</p>	Yes

conclusions of the paper rely must be either included in your submission or deposited in [publicly available repositories](#) (where available and ethically appropriate), referencing such data using a unique identifier in the references and in the “Availability of Data and Materials” section of your manuscript.

Have you have met the above requirement as detailed in our [Minimum Standards Reporting Checklist](#)?

26 **Abstract**

27

28 **Background**

29 Advancements in portable scientific instruments provide promising avenues to expedite  
30 field work in order to understand the diverse array of organisms that inhabit our  
31 planet. Here we tested the feasibility for *in situ* molecular analyses of endemic fauna  
32 using a portable laboratory fitting within a single backpack, in one of the world's most  
33 imperiled biodiversity hotspots: the Ecuadorian Chocó rainforest. We utilized portable  
34 equipment, including the MinION nanopore sequencer (Oxford Nanopore Technologies)  
35 and the miniPCR (miniPCR), to perform DNA extraction, PCR amplification and real-  
36 time DNA barcoding of reptile specimens in the field.

37

38 **Findings**

39 We demonstrate that nanopore sequencing can be implemented in a remote tropical  
40 forest to quickly and accurately identify species using DNA barcoding, as we generated  
41 consensus sequences for species resolution with an accuracy of >99% in less than 24  
42 hours after collecting specimens. The flexibility of our mobile laboratory further allowed  
43 us to generate sequence information at Universidad Tecnológica Indoamérica in Quito  
44 for recently collected rare, endangered, and undescribed specimens. This includes the  
45 recently re-discovered Jambato toad, which was thought to be extinct for 28 years.  
46 Sequences generated on the MinION required as little as 30 reads to achieve high  
47 accuracy relative to Sanger sequencing and with further multiplexing of samples,

1  
2  
3  
4 48 nanopore sequencing can become a cost-effective approach for rapid and portable DNA  
5  
6 49 barcoding.  
7

9 50

## 11 51 **Conclusions**

12  
13  
14 52 Overall, we establish how mobile laboratories and nanopore sequencing can help to  
15  
16 53 accelerate species identification in remote areas to aid in conservation efforts and be  
17  
18  
19 54 applied to research facilities in developing countries. This opens up possibilities for  
20  
21 55 biodiversity research by promoting local research capacity building, teaching laymen  
22  
23  
24 56 and students about the environment, tackling wildlife crime or by promoting  
25  
26 57 conservation via research focused eco-tourism.

## 38 62 **Data Description**

## 43 64 **Background**

44  
45 65 Biodiversity is defined as the variety of life found on Earth, including variation in genes,  
46  
47  
48 66 species, and ecosystems. While about 1.9 million species have been described to date,  
49  
50  
51 67 there are an estimated 5-30 million species in total on the planet, with most of the  
52  
53 68 diversity contained within tropical rainforests [1], [2], [3]. For instance, Ecuador, despite  
54  
55 69 its small size of 283,561 km<sup>2</sup> (roughly 1.5% of South America), is one of the most  
56  
57  
58 70 biologically diverse countries in the world [4], [5]. Biodiversity is fundamentally important

71 to natural and agro-ecosystems; it provides humans with an array of foods and  
72 materials, contributes to medical discoveries, furnishes the economy, and supports  
73 ecological services that make life on our planet possible [6]. Today species are going  
74 extinct at an accelerated rate because of environmental changes caused by human  
75 activities including habitat loss, spread of non-native species, pollution, and climate  
76 change [7], [8]. All of these threats have put a serious strain on the diversity of species  
77 on Earth.

78 In the past decade, an ever-growing body of readily accessible knowledge, coupled  
79 with new tools in molecular genetics and bioinformatics, have resulted in species being  
80 described with greater accuracy, in greater detail, and with additional information to  
81 morphological differences. As a result of this increase in quality and content, desirable  
82 as it is, the actual process of species description has become slower, while the rate at  
83 which species are being lost to extinction has become faster. For many groups of  
84 animals, species delimitation can be challenging using solely morphological  
85 characteristics [9], [10], and can be improved by incorporating molecular data [11], [12].  
86 This is relevant for the conservation of threatened animals because programs or laws  
87 can be implemented more effectively when the existence of a species or population is  
88 formally described. DNA barcoding, which is a diagnostic technique that utilizes short  
89 conserved DNA sequences, has become a popular tool for a variety of studies including  
90 species identification and molecular phylogenetic inference [13], [14], [15]. Ongoing  
91 initiatives, such as 'Barcode of Life' ([www.barcodeoflife.org](http://www.barcodeoflife.org)), seek to identify species  
92 and create large-scale reference databases via diagnostic DNA sequences using a  
93 standardized approach to accelerate taxonomic progress.

1  
2  
3  
4 94 While projects utilizing standard molecular markers have grown in popularity in  
5  
6 95 the last decade, a fundamental challenge remains in transporting biological material to a  
7  
8  
9 96 site that can carry out the DNA sequencing. Furthermore, complex and overwhelming  
10  
11 97 regulations can impede biological research in biodiverse countries, and can make it  
12  
13  
14 98 challenging to export material out of the country of origin [16], [17]. Additionally, many  
15  
16 99 research institutions in developing parts of the world do not have access to conventional  
17  
18  
19 100 sequencing technologies within the country, further limiting identification options. This is  
20  
21 101 the case for Ecuador, where most laboratories ship their samples internationally to be  
22  
23  
24 102 sequenced, often creating a delay of weeks to months between tissue collection and the  
25  
26 103 availability of the sequence data. Performing genetic analyses on site or at a nearby  
27  
28  
29 104 facility within the country can help to avoid project delays and decrease the risk of  
30  
31 105 sample quality decline associated with extensive transport. Now it has become possible  
32  
33 106 to take portable lab equipment to remote regions, perform *in situ* experiments, and  
34  
35  
36 107 obtain genetic information relevant for biological studies and conservation policies in  
37  
38 108 real-time.

### 39 40 41 109 42 43 110 **Portable Sequencing**

44  
45 111 The MinION (Oxford Nanopore Technologies) is a recently developed nanopore-based  
46  
47  
48 112 DNA sequencing platform. This technology has several advantages over traditional  
49  
50  
51 113 sequencing technologies, including long-read output, low initial startup costs relative to  
52  
53 114 other commercial sequencers, portability, and rapid real-time analysis (reviewed by [18],  
54  
55 115 [19]). Due to its small size (10 x 3.2 x 2 cm), light weight (90 grams) and ease of power  
56  
57  
58 116 and data transfer (a single USB connection to a standard laptop computer), the MinION

117 has emerged as a valuable tool for portable sequencing projects. This device has been  
118 applied in remote sites outside of conventional labs including West Africa to monitor the  
119 2014-2015 Ebola outbreak [20] and Brazil for Zika virus outbreak surveillance [21], [22].  
120 It has also been applied in the Arctic to sequence microbial communities [23], [24], in  
121 Tanzania to sequence frog DNA [25], and in Snowdonia National Park for shotgun  
122 genomic sequencing of closely-related plant species [26]. The MinION has even been  
123 run aboard the International Space Station to evaluate performance off-Earth [27],  
124 however, the sequencing runs were performed using DNA libraries pre-prepared in a  
125 standard laboratory environment, whereas preparing samples outside of a lab with  
126 limited infrastructure presents additional challenges. Indeed, nanopore sequencing  
127 appears to hold promise for a variety of molecular experiments in the field.

128         Scientists have mused over the possibility of a portable method for DNA  
129 barcoding for over a decade [28], [15] and in this study our goal was to determine if the  
130 steps involved in barcoding, including real-time sequencing with the MinION, could be  
131 carried out entirely during a field expedition. We specifically targeted DNA barcodes  
132 with existing reference databases because they are the standard approach in molecular  
133 biodiversity studies, and allowed us to rapidly produce genetic data for the identification  
134 of several animal taxa by multiplexing. Our field site was situated in a remote tropical  
135 rainforest and did not offer the commodities of a sophisticated laboratory environment,  
136 including consistent power sources or internet access. Furthermore, we restricted our  
137 laboratory equipment to reasonably affordable technologies. We did this for two  
138 reasons, (a) researchers in the field of molecular ecology may have limited funds for  
139 biodiversity research projects and (b) to test technologies that are affordable for

140 research facilities in developing countries. We assessed the feasibility for *in situ* genetic  
141 sequencing of reptiles and amphibians for rapid species identification, using a portable  
142 laboratory fitting within a single backpack, at one of the world's most imperiled  
143 biodiversity hotspots, the Ecuadorian Chocó rainforest (Fig. 1). We demonstrate that  
144 portable DNA amplicon sequencing with the MinION allows rapid, accurate, and efficient  
145 determination at the species level under remote tropical environmental conditions, as  
146 well as quick turnaround time for DNA barcodes of undescribed and threatened species  
147 at a research facility within the country.

**Analyses**

**Site, sampling, digital photos, tissue collection**

152 We performed all field-based research in the Canandé Reserve (Fig. 1, 0.52993 N,  
153 79.03541 W, 594 m), a 2000 ha. protected area, owned by Jocotoco Foundation  
154 (<http://www.fjocotoco.org/canandeacute1.html>) in Esmeraldas province in Northwestern  
155 Ecuador. The reserve is located in the Chocó ecoregion and is approximately 6 hours  
156 by car, depending on road conditions, from the city of Quito. The majority of organisms  
157 sampled in this study were located by space-constrained visual examination of ground-  
158 level substrates [1]. The remaining individuals were detected by turning over logs,  
159 rocks, and other surface objects. All specimens included in the genetic analyses were  
160 morphologically identified based on [2] and [3]. The sample (a tadpole, CJ 7191) of  
161 *Atelopus ignescens* was provided by the Museum of Centro Jambatu, Ecuador and was  
162 preserved in ethanol 95%. We took vouchers for all samples collected and processed in

**Portable laboratory equipment and set-up**

169 The main items for portable laboratory equipment included the following: two MinION  
170 devices, a USB 3.0 cable, three SpotON flow cells (R9.5, Oxford Nanopore  
171 Technologies (ONT)), one miniPCR thermocycler (miniPCR), and a benchtop centrifuge  
172 (USA Scientific), as well as standard laboratory pipettes and sample racks (Fig. 2,  
173 Supplementary Figure 3). The MinKNOW offline software (ONT) required for operation  
174 of the MinION was installed and ran on a Windows Vaio Sony laptop with an external  
175 SSD drive (VisionTek, 240GB). All heat block and temperature cycling steps were  
176 performed using the miniPCR machine, which is a portable thermo-cycler weighing 0.45  
177 kg. The miniPCR was programmed via an application on the laptop and powered by an  
178 external battery (PowerAdd). The total amount of equipment could fit in one carry-on  
179 backpack; a full list of laboratory hardware is provided as Supplementary Table 1.  
180 Reagents for sequencing required frozen transport from the US, which was attained by  
181 use of packaging with cold packs in a Styrofoam box and was later transferred to a  
182 plastic cool box with further cold packs upon arrival to Quito, Ecuador. MinION flow cells  
183 require storage at +2-8°C and were therefore transferred in a food storage container  
184 with chilled cold packs. At the field site, reagents and supplies were stored inside a local  
185 refrigerator and freezer.

187 **Molecular techniques**

188 Genomic DNA was extracted from fresh blood or tissue samples stored in 95% ethanol  
189 using either the DNeasy Blood & Tissue Kit (Qiagen, Hilden, Germany) according to  
190 manufacturer's protocol and eluted in 100 µl ddH<sub>2</sub>O or a modified salt precipitation  
191 method based on the Puregene DNA purification kit (Gentra Systems) that involved  
192 cellular lysis with SDS and proteinase K, protein precipitation using guanidine  
193 isothiocyanate, and DNA precipitation by isopropanol. Tools for manipulating and lysing  
194 tissues were sterilized with a flame in between processing samples. We amplified the  
195 following mitochondrial DNA fragments: 16S gene using primers 16Sar-L and 16Sbr-H-  
196 R from [4], CytB gene using primers L14910 and H16064 developed by [5], and the  
197 gene coding for subunit 4 of the NADH dehydrogenase with primers ND4 developed by  
198 [6]. All PCR primers contained universal tailed sequences for the Oxford Nanopore  
199 Technologies barcoding kit (Supplementary Table 2). We used the ONT PCR Barcoding  
200 Kit that allows up to 12 different libraries (barcodes 1-12) to be combined and loaded  
201 onto a single flow cell at the same time. PCR reactions contained approximately 1 µl of  
202 PCR product, 2.5 µl 10X PCR buffer, 1 µl 25mM MgCl<sub>2</sub>, 200 µM dNTP mix, 0.2 µM of  
203 each primer and 0.25 Platinum Taq DNA Polymerase (Thermo Fisher Scientific) in a 25  
204 µL total volume. All samples for the first PCR run were amplified on the same miniPCR  
205 under the following settings: initial denaturation: 94°C for 2 minutes, 35 cycles of  
206 denaturation at 94°C for 45 seconds, annealing at 56°C for 60 seconds extension for  
207 72°C for 60 seconds, and a final extension of 72°C for 120 seconds. Then a second  
208 round of PCR was carried out, including 2 µl of ONT PCR Barcode, 2 µL of first-round

1  
2  
3  
4 209 PCR product, 41  $\mu$ l H<sub>2</sub>O, and 50  $\mu$ l PCR reaction mix (0.5  $\mu$ l Taq DNA polymerase, 1  $\mu$ l  
5  
6 210 dNTP mix, 2  $\mu$ l MgCl<sub>2</sub>, 41  $\mu$ l H<sub>2</sub>O). The second round of PCR barcode conditions  
7  
8 211 were modified based on ONT protocol for the Platinum Taq polymerase used in this  
9  
10 212 study as follows: initial denaturation at 95°C for 3 minutes, 15 cycles of denaturation at  
11  
12 213 95°C for 15 seconds, annealing at 62°C for 15 seconds, extension at 72°C for 60  
13  
14 214 seconds, and final extension at 72°C for 120 seconds. For verification of samples  
15  
16 215 sequenced in the field, PCR products were subsequently cleaned with Exonuclease I and  
17  
18 216 Alkaline Phosphatase (Illustra ExoProStar by GE Healthcare) at the Universidad  
19  
20 217 Tecnológica Indoamérica (UTI) in Quito and sent to Macrogen Inc (Korea) for Sanger  
21  
22 218 sequencing. All PCR products were sequenced on an ABI3730XL sequencer in both  
23  
24 219 forward and reverse directions with the same primers that were used for amplification.  
25  
26 220 The created sequences were deposited in GenBank (and will be available upon  
27  
28 221 publication). All original Sanger and MinION generated consensus sequences can be  
29  
30 222 found in Additional File 1.

#### 40 224 **MinION sequencing**

41 225 DNA library preparation was carried out according to the 1D PCR barcoding amplicons  
42  
43 226 SQK-LSK108 protocol (Oxford Nanopore Technologies). Barcode DNA products were  
44  
45 227 pooled with 5  $\mu$ l of DNA CS control and an end-repair was performed (NEB-Next Ultra II  
46  
47 228 End-prep reaction buffer and enzyme mix, New England Biolabs), then purified using  
48  
49 229 AMPure XP beads. Adapter ligation and tethering was then carried out with 20  $\mu$ l  
50  
51 230 Adapter Mix (ONT) and 50  $\mu$ l of NEB Blunt/TA ligation Master Mix (New England  
52  
53 231 Biolabs). The adapter ligated DNA library was then purified with AMPure beads,

232 followed by the addition of Adapter Bead binding buffer (ONT), and finally eluted in 15  $\mu$   
233 of Elution Buffer (ONT). Each R9 flow cell was primed with 1000  $\mu$ l of a mixture of Fuel  
234 Mix (Oxford Nanopore Technologies) and nuclease-free water. Twelve microliters of the  
235 amplicon library was diluted in 75  $\mu$ L of running buffer with 35  $\mu$ L RBF, 25.5  $\mu$ L LLB,  
236 and 2.5  $\mu$ L nuclease-free water and then added to the flow cell via the SpotON sample  
237 port. The “NC\_48Hr\_sequencing\_FLO-MIN107\_SQK-LSK108\_plus\_Basecaller.py”  
238 protocol was initiated using the MinION control software, MinKNOW (offline version  
239 provided by ONT).

241 **Bioinformatics**

242 The commands used can be found in the Supplementary Materials and Methods  
243 section.

244 To retrieve the nucleotide sequences from raw signal data generated by the MinKNOW  
245 software, we used Albacore 1.2.5 (<https://github.com/dvera/albacore>) for base calling  
246 and de-multiplexing of the ONT barcodes. The FAST5 files were then converted to fastq  
247 files using Nanopolish [7]; (<https://github.com/jts/nanopolish>). We then filtered the raw  
248 reads for quality (score of >13) and read length (> 200bp) using Nanofilt  
249 (<https://github.com/wdecoester/nanofilt>), and generated consensus sequences using both  
250 reference-based mapping and *de novo* assembly. For the reference-based mapping we  
251 used BWA 0.7.15 [8]; (<https://github.com/lh3/bwa/releases>) to align the reads to the  
252 reference, samtools 1.3 [9] to process the mapping file, and ANGSD [10], to call the  
253 consensus sequence. The *de novo* assembly of each amplicon was carried out using  
254 Canu [11], (<https://canu.readthedocs.io>), with parameters fitting for our application. Given

1  
2  
3  
4 255 that we used short amplicons for the assembly we set the minimum read length to  
5  
6 256 200bp and the minimum overlap to 50bp. We subsequently extracted the consensus  
7  
8  
9 257 sequences using tgStoreDump. After the consensus calling (for both methods) we  
10  
11 258 mapped the reads back to the consensus sequence (using BWA mem and samtools as  
12  
13  
14 259 described above) and polished the sequencing using Nanopolish [7]. Adapters were  
15  
16 260 removed using Cutadapt [12]. The consensi were then aligned to the Sanger sequences  
17  
18  
19 261 of the same amplicons to investigate the quality of the consensus sequences generated  
20  
21 262 from MinION reads using SeaView [13] and AliView [14]. Sanger sequencing reads  
22  
23  
24 263 were edited and assembled using Geneious R10 software [15] and mapping files  
25  
26 264 inspected by eye using Tablet [16].  
27

28  
29 265 We further tested the impact of coverage on the consensus accuracy by  
30  
31 266 randomly subsampling three sets of 30, 100, 300 and 1,000 reads, respectively for the  
32  
33 267 eyelash palm pitviper and gecko 1. Subsampling was performed with famas  
34  
35  
36 268 (<https://github.com/andreas-wilm/famas>). These sets were assembled *de novo* and  
37  
38 269 processed using the same approach we used for the full data sets (see above).  
39

40  
41 270 We then created species alignments for all barcodes (using sequences obtained  
42  
43 271 from Genbank; accession numbers can be found in the phylogenetic tree  
44  
45  
46 272 reconstructions in the Supplementary material). We inferred the best substitution model  
47  
48 273 using jModelTest [17] and reconstructed their phylogenetic trees using the maximum  
49  
50 274 likelihood approach implemented in Mega 5 [18] with 1,000 bootstrap replicates (for  
51  
52  
53 275 bioinformatics workflow see Fig. 3). The output tree files including the Genbank  
54  
55 276 Accession Numbers are provided in the supplementary material.

278 **Discussion**

279

280 **From Snakes to Sequences in 24 Hours**

281 On July 11, 2017, we arrived at the field site at approximately 1500 hours and collected  
282 reptile and amphibian samples from 2000 to 2300 hours. Next, back at the field station,  
283 we extracted DNA and performed PCR amplification for 16S, CytB, and ND4 genes. On  
284 July 12, the PCR barcodes were pooled, the library was prepared, and then sequencing  
285 was initiated at approximately 1600 hours on a flow cell using the offline MinKNOW  
286 software, generating 16,663 reads after approximately two hours (Fig. 2). The software  
287 was then paused in order to assess the reads generated. Within 24 hours of collecting  
288 reptiles and amphibians in the Ecuadorian Chocó, we successfully generated  
289 consensus sequences for 16S and ND4 genes of an eyelash palm pitviper (*Bothriechis*  
290 *schlegelii*) and 16S for the dwarf gecko (*Lepidoblepharis* sp.; gecko 1). The CytB gene  
291 was not successfully sequenced, which was later confirmed at UTI's lab by lack of PCR  
292 product on a gel (Supplementary Figure 1). The field-generated sequence data was  
293 analyzed that evening on a laptop using a number of open source and custom-  
294 developed bioinformatic workflows (see Materials and Methods; Supplementary Figure  
295 2). Blasting of the sequences against the NCBI database, as well as constructing  
296 phylogenetic trees using the nanopore sequences and previously generated reference  
297 database yielded accurate species identifications and phylogenetic placements (Fig. 3  
298 and Fig. 4).

299       Upon returning to a local research facility in Quito, the Universidad Tecnológica  
300 Indoamérica, which does not have local sequencing capacities, we created one

301 additional DNA barcode library with new samples. With our remaining flow cell, we were  
302 interested in quickly generating genetic information for (a) additional specimens that  
303 were collected during our field expedition (gecko 2), (b) undescribed species collected  
304 the week before our expedition (Genera: *Dipsas* and *Sibon*), (c) an endangered species  
305 that would have been difficult to export out of the country (Jambato toad), (d) a rare  
306 species lacking molecular data (Guayaquil blind snake), and (e) combinations of  
307 barcoded samples through multiplexing (for the eyelash palm pitviper and gecko 1).  
308 Initially, this second sequencing run appeared to perform well. However, after using  
309 Albacore to demultiplex the reads, we determined the adapter ligation enzyme likely  
310 degraded because the output primarily consisted of adapter sequences (Supplementary  
311 Figure 1). Nevertheless, we were able to generate consensus sequences for 16S of the  
312 Jambato toad, the two *Dipsas* species, the dwarf gecko, and the Guayaquil blind snake  
313 (Fig. 3 and Fig. 4). The reads from both sequencing runs are available at Genbank  
314 (pending).

315  
**316 Subsampling**

317 Next, we investigated the read depth needed to call accurate consensus sequences  
318 using our approach. We used the eyelash palm pitviper and gecko 1 to test  
319 subsampling schemes, since we obtained thousands of reads for these samples. We  
320 randomly subsampled to 30, 100, 300 and 1,000 reads (in three replicates; see  
321 Supplementary Table 3). For the eyelash palm pitviper we achieved accuracies ranging  
322 from 99.4% to 99.8% using only 30 reads, 99.6% to 100% using 100 reads, 99.8% for  
323 300 reads and 99.8% to 100% for 1,000 reads. For gecko 1 we achieved even better

324 accuracy overall, with 30 reads ranging from 99.4% to 99.8%, 100 reads from 99.8% to  
325 100%, all 300 reads sets achieved an accuracy of 100% and for 1,000 reads all but one  
326 set (99.8%) achieved 100% accuracy.

327

328 **Performance in the field**

329 Our objective was to employ a portable laboratory in a rainforest to identify endemic  
330 species with DNA barcoding in real-time (Fig. 2). Our protocols resulted in successful  
331 DNA extraction, PCR amplification, nanopore sequencing, and barcode assembly. We  
332 observed that the MinION sequencing platform performed well in the field after  
333 extended travel, indicating the potential for nanopore-based sequencing on future field  
334 expeditions. Although we demonstrate that the successful molecular identification of  
335 organisms in a remote tropical environment is possible, challenges with molecular work  
336 in the field remain. Our field site was provided with inconsistent electrical power, but still  
337 allowed us to use a conventional small centrifuge for several steps of DNA extraction  
338 and to power a refrigerator for storage of flow cells and some of the reagents, although  
339 temperatures were likely suboptimal. Lack of electrical supply can impede adequate  
340 storage of temperature-sensitive reagents for extended periods of time. Our  
341 experiments were performed during a relatively short field trial, with 10 days being the  
342 longest time period that reagents were kept at inconsistent freezing temperatures. It is  
343 uncertain how well nanopore kit reagents or flow cell integrity would endure over longer  
344 periods without consistent cooling temperatures, and we suspect the adapter ligation  
345 enzyme was compromised during our second nanopore run, as demultiplexing led to a  
346 majority of barcode adapters in each folder (Supplementary Figure 1). Furthermore, we

347 used an external SSD drive with 240 GB space to store raw data generated by  
348 MinKNOW. Due to overheating of the external drive, we placed ice packs underneath  
349 the USB stick to maintain cooler temperatures, which appeared to maintain the run.

350 While the MinION sequencer fits in the palm of a hand and needs only a USB  
351 outlet to function, bioinformatic analyses can be hampered under remote field  
352 conditions, because internet access, large amounts of data storage, and long periods of  
353 time are often required for such analytical tasks. In our study, utilizing short DNA  
354 fragments with a relatively small number of samples for barcoding allowed us to perform  
355 all bioinformatic analyses in the field, but larger data outputs may require additional  
356 storage and more computational resources.

357  
358 **Implications for conservation and biodiversity assessments**

359 Tropical rainforests, such as the Ecuadorian Chocó, are often rich in biodiversity, as  
360 well as species of conservation concern. The Chocó biogeographical region is one of  
361 the world's 25 biodiversity hotspots [29] and several studies have identified the Chocó  
362 region of western Colombia and Ecuador as a global conservation priority [29], [30],  
363 [31]. We therefore chose this region for proof of principle *in situ* molecular work to  
364 highlight the importance of expediting fieldwork in order to produce genetic information  
365 of endemic fauna. Our rapidly obtained DNA barcodes allowed us to accurately identify  
366 organisms while in the field. When samples are not required to be exported out of the  
367 country to carry out molecular experiments, real-time sequencing information can  
368 contribute to more efficient production of biodiversity reports that advise conservation  
369 policy, especially in areas of high conservation risk.

370 Of particular note in this study was the critically endangered harlequin Jambato  
371 toad, *Atelopus ignescens*. Although not a denizen of the Chocó rainforests, this Andean  
372 toad is a good example to demonstrate how nanopore sequencing can aid in the  
373 conservation of critically endangered species. *Atelopus ignescens* was previously  
374 presumed extinct (it is currently still listed as “extinct” on IUCN; [32]) and was only  
375 recently rediscovered [33]. The last confirmed record of *Atelopus ignescens* dates back  
376 to 1988, and this species was presumed to be extinct before one population was  
377 rediscovered in 2016, 28 years later. *Atelopus* is a species-rich genus of neotropical  
378 toads containing 96 species, most of which are possibly extinct or endangered. In  
379 Ecuador there are 11 species of *Atelopus* that are Critically Endangered (tagged as  
380 Possibly extinct; [34]). Extinctions of *Atelopus* (and other anurans) are beyond control  
381 and are increasingly exacerbated by a combination of factors including habitat loss,  
382 climate change and pathogens [35], [36], [37]. For the many endangered species that  
383 are protected by international laws and treaties, sample transport requires permits that  
384 can often be difficult to obtain, even when research is expressly aimed at conservation,  
385 resulting in project delays that can further compromise sample quality. By working within  
386 the country, under permits issued by Ministerio del Ambiente de Ecuador to local  
387 institutions, we were able to generate sequence data for the endangered harlequin  
388 Jambato toad *Atelopus ignescens* within 24 hours of receiving the tissue, whereas  
389 obtaining permits to ship samples internationally in the same time frame would have not  
390 been possible. Rapidly identifying the phylogenetic affinity of populations of *Atelopus*  
391 toads could speed up conservation efforts for these animals. Namely, a better  
392 understanding of the systematics of the group facilitated by real-time sequencing could

393 help establish species limits, geographic distributions, in-situ conservation actions and  
394 ex-situ breeding programs.

395

396 **Species identifications**

397 It is important to note that we do not intend for rapidly-obtained portable sequence  
398 information to substitute for standard species description processes. Instead, we aim to  
399 demonstrate that obtaining real-time genetic information can have beneficial  
400 applications for biologists in the field, such as raising the interesting possibility of  
401 promptly identifying new candidate species, information which can be used to adjust  
402 fieldwork strategies or sampling efforts. As we have shown, the latter could be  
403 especially important with organisms and habitats facing pressing threat. Rapidly  
404 obtaining genetic sequence information in the field can also be useful for a range of  
405 other applications, including identifying cryptic species, hybrid zones, immature stages,  
406 and species-complexes.

407         Furthermore, we acknowledge that in most cases multiple loci are needed to  
408 reliably infer species position in a phylogenetic tree. DNA barcoding has been shown to  
409 hold promise for identification purposes in taxonomically well-sampled clades, but may  
410 have limitations or pitfalls in delineating closely related species or in taxonomically  
411 understudied groups [38], [39]. However, our aim in this study was to demonstrate that  
412 portable sequencing can be used in the field and that the final sequences have an  
413 accuracy needed to achieve reliable identification of a specimen. While a recent study  
414 has demonstrated a field-based shotgun genome approach with the MinION to identify  
415 closely related plant species [26], DNA barcoding already offers a robust reference

416 database for many taxa thanks in part to global barcoding initiatives (the current  
417 Barcode of Life Data System contains 4,013,927 specimens and 398,087 Barcode  
418 Index Numbers <http://ibol.org/resources/barcode-library/> as of September 2017).

419 Finally, while highlighting the value of real-time portable DNA barcoding in this  
420 study, we do not wish to downplay the significance of taxonomic experts, who have  
421 invaluable specialist knowledge about specific groups of organisms. Even with the  
422 advent of molecular diagnostic techniques to describe and discover species, placing  
423 organisms within a phylogenetic context based on a solid taxonomic foundation is  
424 necessary. An integrative approach utilizing molecular data and morphological  
425 taxonomy can lead to greater insight of biological and ecological questions [40]. As  
426 noted by Bik, 2017, *“There is much to gain and little to lose by deeply integrating  
427 morphological taxonomy with high-throughput sequencing and computational  
428 workflows.”*

429  
430 **Bioinformatic challenges**

431 While we were able to show that nanopore sequencing results in high quality DNA  
432 barcode sequences, some challenges during the read processing remain. To our  
433 knowledge, no software solution specifically designed to assemble DNA barcodes from  
434 long read technologies is available. Here, we created our own pipeline (Supplementary  
435 Figure 2). This required changing the settings for Canu [41], a whole genome *de novo*  
436 assembler (see Materials and Methods in the Supplementary Information; and  
437 discussion below). However, software geared towards the specifics of assembling DNA

438 barcodes from long read data would be beneficial to make the bioinformatics analysis  
439 easier and more widely applicable.

440 We were also interested in investigating the minimum coverage needed to create  
441 reliable consensus sequences. Therefore, we used different subsampling schemes.  
442 Overall, a coverage of 30 reads achieved an accuracy of 99.4 - 99.8%. With 100x read  
443 coverage almost all assemblies were 100% accurate, indicating that an excessive  
444 number of reads is not needed to produce high quality consensus sequences.  
445 Furthermore, we applied Nanopolish to all consensus sequences. This tool has been  
446 shown to be very effective at correcting typical nanopore errors, such as homopolymer  
447 errors [42], [43]. As can be seen in section "Post-Nanopolish assembly identity" in [43],  
448 accuracy of the resulting consensus increases significantly after polishing. While, we did  
449 not measure the improvement in accuracy in our study, we did notice a high accuracy  
450 after polishing. However, as can be seen in Fig. 4B, nanopolish is not always able to  
451 accurately correct homopolymer stretches.

452 We further tested reference-based mapping versus *de novo* assembly, because  
453 a reference-based mapping approach may introduce bias, making it possible to miss  
454 indels. Overall, we see that consensus sequences generated using reference-based  
455 mapping have slightly lower accuracy. However, in two cases (the eyelash palm pitviper  
456 and the Jambato toad) an accuracy of 100% was achieved with reference-based  
457 mapping. Interestingly, in the case of *Dipsas* sp. (JMG378), reference-based mapping  
458 resulted in a slightly better accuracy than the *de novo* approach (99.4% compared to  
459 99%). However, in general, we recommend the use of a *de novo* assembly approach as  
460 this method can be applied even if no reference sequence is available and generally

461 produced more accurate sequences. An alternative approach would be to generate  
462 consensus sequences by aligning the individual reads for each barcode to one another,  
463 which would not be affected by a reference bias. This method is implemented in the  
464 freely available software tool Allele Wrangler ([https://github.com/transplantation-](https://github.com/transplantation-immunology/allele-wrangler/)  
465 [immunology/allele-wrangler/](https://github.com/transplantation-immunology/allele-wrangler/)). However, at the time of submission this tool picks the first  
466 read as the pseudo reference, which can lead to errors in the consensus if this read is  
467 of particularly low quality or an incorrect (contaminant) sequence. Future developments  
468 might establish this method as an alternative to *de novo* assembly algorithms, which are  
469 typically written for larger genomes (e.g. the minimum genome size in Canu is 1000bp)  
470 and can have issues with assemblies where the consensus sequence is roughly the  
471 size of the input reads (*personal communications* Adam Phillippy).

472         Each of our two runs showed a very high number of reads not assigned to any  
473 barcode sequence after de-multiplexing with Albacore 1.2.5 (7,780 and 14,272 for the  
474 first and second sequencing run, respectively). In order to investigate whether these  
475 reads belong to the target DNA barcodes but did not get assigned to sequencing  
476 barcodes, or if they constitute other sequences, we generated two references (one for  
477 each sequencing run) comprising all consensi found within each individual sequencing  
478 run. We then mapped all reads not assigned to barcodes back to the reference. We  
479 were able to map 2,874 and 4,997 reads to the reference for the first and the second  
480 sequencing run, respectively, which shows that a high number of reads might be usable  
481 if more efficient de-multiplexing algorithms become available. Here we used Albacore  
482 1.2.5, an ONT software tool, to de-multiplex the sequencing barcodes. This tool is under  
483 constant development and thus might offer more efficient de-multiplexing in later

4884 versions. Alternatively, 3rd party software tools like npBarcode [44] or Porechop  
4885 (<https://github.com/rrwick/Porechop>) can be used.

4886

**4887 Cost-effectiveness and local resource development**

4888 Next-generation sequencing technologies are constantly evolving, along with their  
4889 associated costs. Most major next-generation sequencing platforms require  
4890 considerable initial investment in the sequencers themselves, costing hundreds of  
4891 thousands of dollars, which is why they are often consolidated to sequencing centers at  
4892 the institutional level [45]. In this study, we used the ONT starter pack, which currently  
4893 costs \$1000, and includes two flow cells and a library preparation kit (6 library  
4894 preparations), as well as the ONT 12 barcoding kit which is currently \$250 for 6 library  
4895 preparations (for a full list of equipment and additional reagents see Supplementary  
4896 Table 1). Using this minimal setup, each barcode sequence costs about \$45 (this  
4897 includes cost for the starter pack, etc; a detailed cost account can be found in the  
4898 Supplementary material). At this cost, further multiplexing of samples on each flow cell  
4899 is necessary to achieve a cost-effectiveness for DNA sequencing relative to other  
4900 commercial options. Fortunately, ONT also offers a 96 barcode kit, currently priced at  
4901 \$1,700. While this is a higher upfront cost it can reduce the price for each DNA barcode  
4902 sequence to about \$12. However, it will not be long until much higher multiplexing (>300  
4903 samples) becomes achievable. This way per DNA barcode costs can be reduced to less  
4904 than \$1. On the contrary, Sanger sequencing from UTI shipped internationally for  
4905 processing costs approximately \$10 per sample, independent of the through-put. Thus,  
4906 the Oxford Nanopore MinION has the potential to be a cost-effective sequencing option

507 for resource-limited labs, especially in developing countries without access to standard  
508 sequencing devices.

509         The small size and low power requirements of the MinION will likely continue to  
510 enable its evolution as a field-deployable DNA sequencing device, opening up new  
511 avenues for biological research in areas where the typical laboratory infrastructure for  
512 genetic sequencing is unavailable. With some training, in the field molecular analyses  
513 could also potentially be performed by students (see [46]) or assistants, providing an  
514 opportunity for local teaching and research capacity building, and community  
515 involvement via research focused ecotourism or citizen-science projects.

516

517 **Future outlook**

518 Technological developments in lab equipment and reagent chemistry are increasingly  
519 enabling the incorporation of genetic analyses into field projects. Several portable  
520 technologies have been used to perform molecular experiments in the field, particularly  
521 for disease diagnostics [47], [48]. Advances in lyophilized and room-temperature  
522 reagents are also promising for field applications, such as EZ PCR Master Mix [49], and  
523 loop-mediated isothermal amplification [50], [51]. A hand-powered centrifuge [52] could  
524 also act as substitute for a standard benchtop centrifuge during DNA extraction steps.  
525 Automatic devices, such as VolTRAX (a compact microfluidic device designed to  
526 automate nanopore library preparation, ONT) and improved library construction  
527 methods may offer faster and high-throughput methods for preparing nanopore libraries  
528 in the future. As the ONT MinION evolves, it could greatly advance field researchers'  
529 capacity to obtain genetic data from wild organisms while in the field. These

530 technologies currently depend on reagents that require freezing, but can be used at field  
531 sites with solar or portable freezer options. Faster and more automated sample  
532 processing, as well as cost reductions, are needed for adoption in low-income settings.

533           Beyond short PCR-based amplicons aimed at species identification, other  
534 exciting potential applications of nanopore sequencing in the field include sequencing of  
535 entire mitochondria from gDNA samples [53] or via long-range PCR, shotgun genome  
536 sequencing [26], analysis of environmental DNA [54], [24], sequencing of direct RNA  
537 [55], [56] or cDNA to rapidly profile transcriptomes ([57], and pathogen diagnostics and  
538 monitoring (such as chytrid fungus; [58]). Rapid portable sequencing can also be  
539 applied to wildlife crime to perform species identification of animals affected by illegal  
540 trafficking, as well as serve to aid in early detection of invasive species threatening local  
541 biodiversity and agriculture, and emerging infectious diseases.

542

543 **Potential implications**

544 Portable DNA barcoding with the MinION sequencer allows rapid, accurate, and  
545 efficient determination at the species level under remote and tropical environmental  
546 conditions. We also demonstrate that portable sequencing can allow nimble use of  
547 rapidly generating data for endangered, rare, and undescribed species at nearby  
548 facilities within the country. In the context of conservation and biodiversity science,  
549 portable nanopore sequencing can be beneficial for applications including:

550

- 551           i. When it is exceedingly challenging or not possible to export biological material  
552           internationally or to a facility with a conventional sequencing device. Be aware

553 that the proper permits to collect samples and carry out experiments in the  
554 location of the study are still necessary, and collaborating with local researchers  
555 is strongly encouraged.

556 ii. When the material to be sequenced may be compromised during  
557 transportation conditions, or during the time in between collection and  
558 sequencing. This can be applicable to experiments involving RNA in particular,  
559 which is subject to degradation if not adequately preserved or immediately  
560 frozen.

561 iii. For biodiversity reports aimed at quickly generating species data to inform  
562 conservation policy decisions, especially in areas of high conservation risk.

563 iv. To rapidly screen and sequence pathogens, such as chytrid fungus in  
564 amphibians or infectious agents in fecal samples. Studies using the MinION in  
565 the field have been applied during epidemics, including recent outbreaks of Ebola  
566 and Zika, and can be applied to non-human pathogens as well.

567 v. To perform on-site identification of organisms, immature life stages, or sexes  
568 that are difficult to distinguish morphologically, such as larvae or pupae of  
569 insects, plants when they are not actively flowering such as orchids, or cryptic  
570 species. This can help guide specimen collection in the field.

571 vi. To assist with rapid species identification in the fight against illegal wildlife  
572 trade.

573 vii. To identify organisms in the field that are difficult to locate or capture by  
574 sampling environmental DNA (eDNA).

575           viii. To build up local sequencing capacity of laboratories and field stations in  
576           developing countries, and to promote training of local students or citizen-science  
577           (e.g. via research focused eco-tourism).

578  
579   While we live in a period of amazing technological change, biodiversity and ecosystem  
580   health are decreasing worldwide. Portable sequencing will not be a silver bullet for  
581   conservation biology, but it can be a powerful tool to more efficiently obtain information  
582   about the diversity of life on our planet. This is particularly important for many  
583   biodiversity hotpots, such as tropical rainforests like the Ecuadorian Chocó, which are  
584   often under high risk of habitat loss. We anticipate that as portable technologies develop  
585   further, this method will broaden the utility of biological field analyses including real-time  
586   species identification, cryptic species discovery, biodiversity conservation reports,  
587   pathogen detection, and environmental studies.

588  
589   **Competing interests**

590   The authors report no competing interests.

591  
592   **Author contributions**

593   AP and SP designed the project. AP, NP, AA, LB, FP, CB, DV and SP carried out  
594   specimen collection; AP and NP laboratory work; AA, LB, FP, LC, CB and DV  
595   morphological species identification and SP computational analyses. AP, NP, AA, LB,  
596   FP, LC, CB, DV and SP wrote the paper.

598 **Acknowledgements**

599  
600 Fieldwork for this project was made possible with the support of Tropical Herping and  
601 Universidad Tecnológica Indoamérica. For granting access to the Canandé reserve, we  
602 are grateful to Martin Schaefer of Fundación Jocotoco. Funding for equipment and  
603 reagents was supported by the National Geographic Society / Waitt grant (W412-15).  
604 Travel funding for Stefan Probst was provided by the Program of Conservation Genomics  
605 at Stanford University. Laboratory work was carried out at Universidad Tecnológica  
606 Indoamérica in Quito. Research and collection permits were issued by the Ministerio del  
607 Ambiente de Ecuador (MAE-DNB-CM-2015-0017). The Jambato toad tissue was  
608 provided by the Museum of Centro Jambatu under the Ministerio del Ambiente de  
609 Ecuador project “Conservation of Ecuadorian amphibian diversity and sustainable use  
610 of its genetic resources.” We thank Oxford Nanopore Technologies for providing  
611 technical support, making the offline MinKNOW software available, and for providing  
612 two free flow cells. We also thank Hitomi Asahara and the UC Berkeley DNA  
613 Sequencing Facility for lending the benchtop centrifuge used in this study; Jared  
614 Simpson, Sergey Koren and Adam Phillippy for very helpful advice and discussion on  
615 the bioinformatic pipeline, and Ellie E. Armstrong for valuable input on the manuscript.
