Lifetime risk of atrial fibrillation according to levels of risk factors

Suppl. Methods. Statistical methods for lifetime risk prediction model and multiple imputation.

Statistical methods for the atrial fibrillation lifetime risk prediction model

We developed a prediction model for the lifetime risk of atrial fibrillation (AF) at the index age 55 years. We used a multivariable Fine-Gray model accounting for the competing risk of death.[1] We included 9 covariates: Body mass index (BMI), systolic blood pressure, and diastolic blood pressure as continuous variables, and sex, smoking (never, past, or current), alcohol intake (optimal or elevated), diabetes (optimal, borderline, or elevated), treatment for hypertension, and history of myocardial infarction or heart failure as categorical variables. We did not perform any variable selection. We checked the assumptions of the Fine and Gray model.[2] We used goodness-of-fit test procedures based on the cumulative sums of residuals to assess the linear functional forms for BMI, systolic blood pressure, and diastolic blood pressure. All were satisfied. We also tested the proportionality of subdistribution hazards for the Fine and Gray model.[2,3] We found that the proportional hazards assumption was violated for BMI, sex, smoking, and history of myocardial infarction or heart failure. As a consequence, we added time-varying covariates $Z \times \log(t)$ to the model, i.e. an interaction term between each of these 4 covariates and the natural logarithmic transformation of time.

We used the cumulative subdistribution baseline hazard and the estimated regression coefficients of the Fine and Gray model to derive the predicted cumulative incidence of AF at age 95 years for 16 risk profiles, in men and women separately.[4] We defined the profiles according to treatment for hypertension (yes or no), BMI (25 kg/m² or 35 kg/m²), alcohol (elevated or optimal), and history of myocardial infarction or heart failure (yes or no). For each profile, we considered a participant with an average blood pressure level (mean systolic blood pressure 128 mm Hg and 124 mm Hg and mean diastolic blood pressure 80 mm Hg and 76 mm Hg for men and women respectively), who never smoked, and had no diabetes. Finally, we assessed the calibration and discrimination of the model. We plotted the AF lifetime risk estimate, computed within deciles of the predicted lifetime risk, against the average of the predicted AF lifetime risk within the same deciles.[5] We assessed discrimination by the c-index adapted for competing risk data.[6] These analyses were conducted in R 3.3.2 *cmprsk*, *crskdiag*, and *pec* packages.

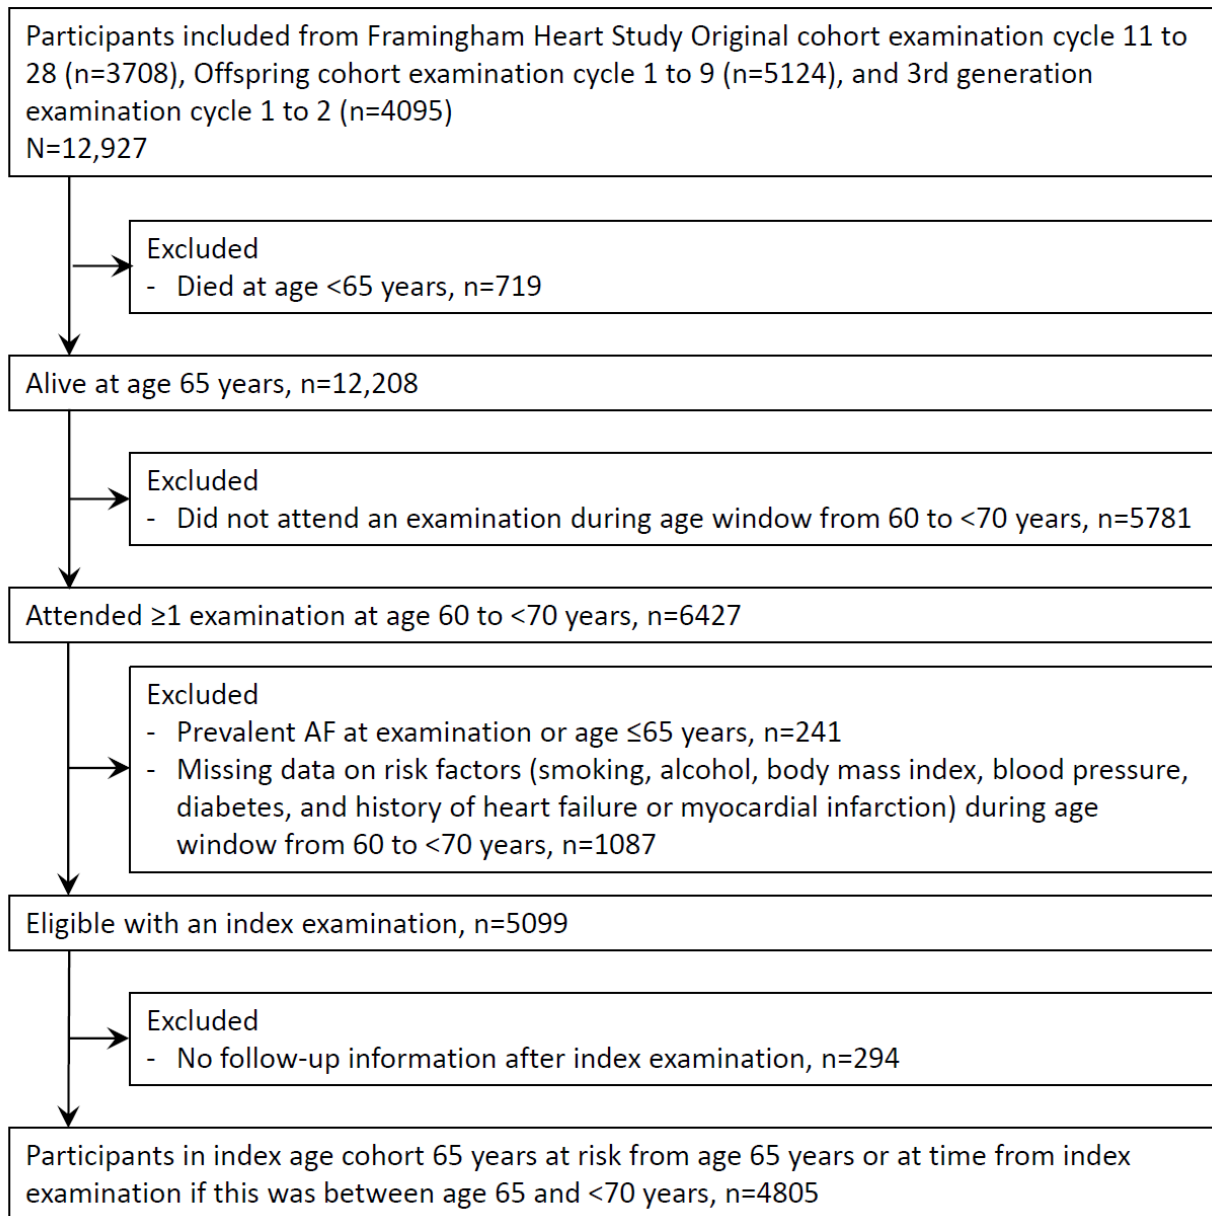

Lifetime risk of atrial fibrillation according to levels of risk factors

Multiple imputation analysis

We included 6778 participants (1201 AF cases), as compared to 5338 participants (489 AF cases) in the complete case analysis. Data were missing for the following 7 risk factors: diabetes (categorical; proportion of missing values 20.4%), BMI (continuous; 5.5%), smoking (categorical; 5.3%), treatment for hypertension (binary; 5.2%), systolic blood pressure (continuous; 0.1%), diastolic blood pressure (continuous; 0.1%), and alcohol (binary; 1.1%). We generated 25 imputed datasets by multiple imputation predictive mean matching method.[7] We included the following covariates in the predictive mean matching model: sex, age, BMI, diabetes, smoking, alcohol, systolic blood pressure, diastolic blood pressure, treatment for hypertension, history of myocardial infarction or heart failure. In addition, we used a generalization of the method proposed by White and Royston:[8] we included the outcome status variable (AF, death, censored), as well as the estimated subdistribution cumulative baseline hazards for AF and death, in the predictive mean matching model. In each imputed dataset, we categorized individuals into optimal, borderline, and elevated aggregated risk categories. The mean percentage, across the 25 imputed datasets, of individuals categorized into optimal, borderline, and elevated groups were 4.1%, 24.7%, and 71.2%, respectively. In each of the 25 imputed datasets, we estimated the lifetime risk at index age 55 years, and the associated standard error, for the optimal, borderline, and elevated risk categories, respectively. For each risk category, we combined the 25 estimates according to Rubin's rules.[9] Finally, we compared the multiple imputation analysis results with the complete case analysis results. The multiple imputation analysis was conducted by R 3.3.2 *cmprsk*, *survival*, *mice*, and *Amelia* packages.

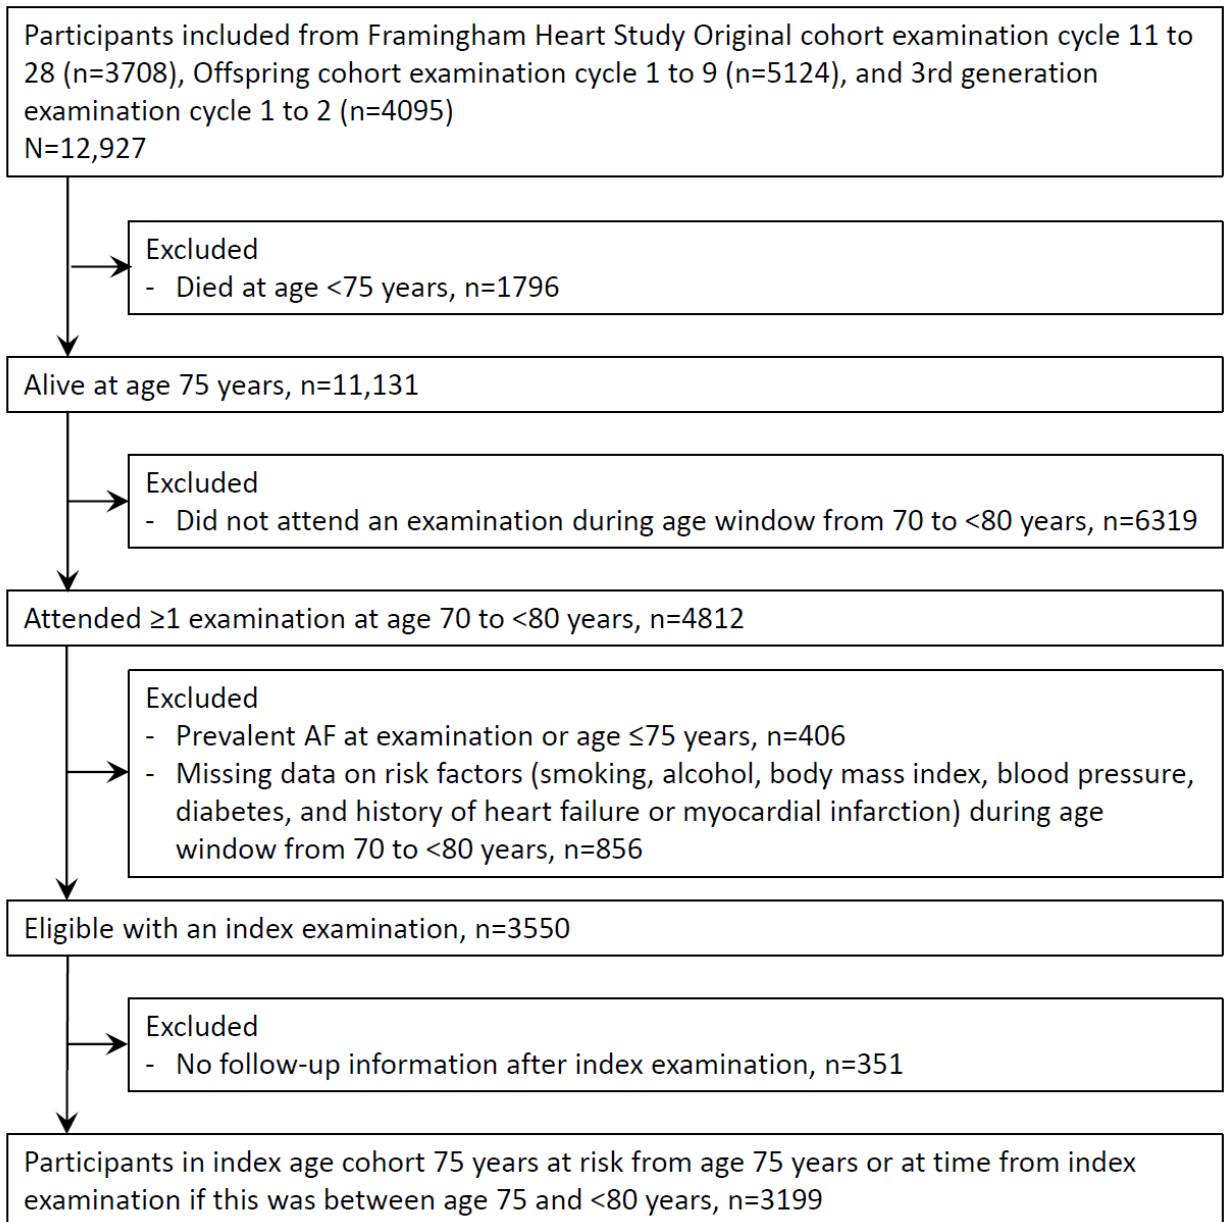

Lifetime risk of atrial fibrillation according to levels of risk factors

Suppl. Figure 1. Selection of the study sample with index age 65 years.

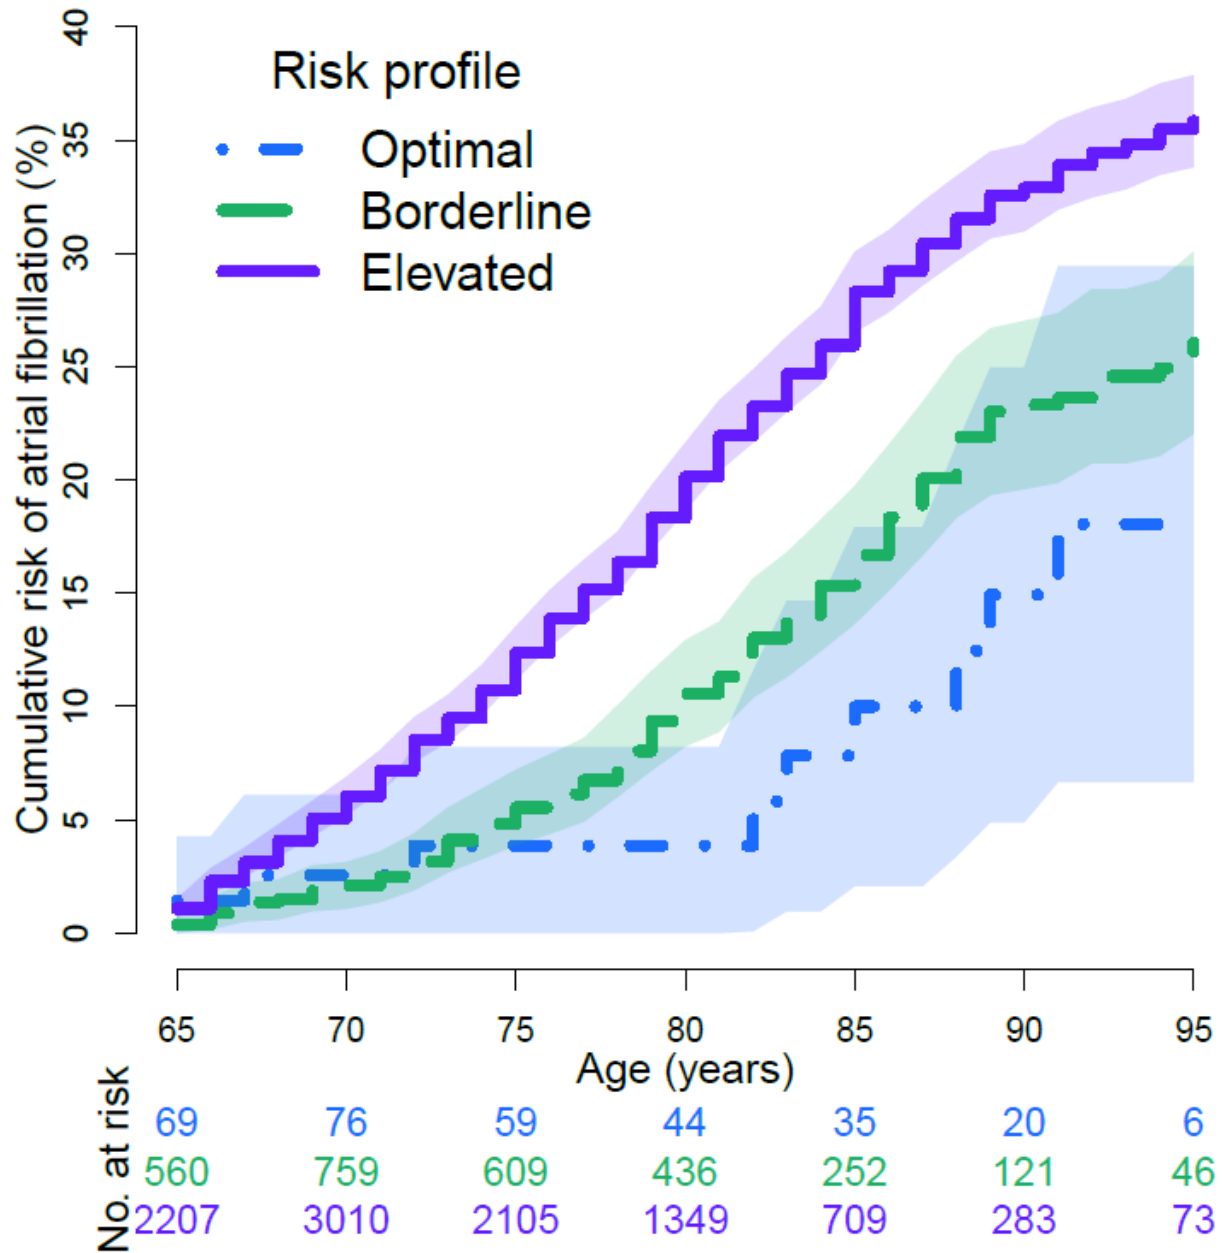

Lifetime risk of atrial fibrillation according to levels of risk factors

Suppl. Figure 2. Selection of the study sample with index age 75 years.

Lifetime risk of atrial fibrillation according to levels of risk factors

Suppl. Figure 3. Cumulative risk for atrial fibrillation according to risk factor burden (optimal, borderline, or elevated) at index age 65 years.

Shadings are 95% confidence boundaries. Participants entered the study sample between age 65 and 70 years; therefore, the number at risk increased from age 65 years to age 70 years.

Lifetime risk of atrial fibrillation according to levels of risk factors

Suppl. Figure 4. Cumulative risk for atrial fibrillation according to risk factor burden (optimal, borderline, or elevated) at index age 75 years.

Shadings are 95% confidence boundaries. Participants entered the study sample between age 75 and 80 years; therefore, the number at risk increased from age 75 years to age 80 years.

Lifetime risk of atrial fibrillation according to levels of risk factors

Suppl. Figure 5. Calibration plot of the prediction model for predicting lifetime risk at index age 55 years.

X-axis is the mean lifetime risk by Fine and Gray model adjusting competing risk of death, y-axis is the actual lifetime risk calculated by *cuminc* function in R *cmprsk* package in each decile of predicted lifetime risk.

Calibration was good, although the lifetime risk is slightly underestimated for moderate lifetime risk groups and overestimated for participants in the highest lifetime risk group. In addition, the C index for lifetime risk at index age 55 years adjusting competing risk of death is 59.4%, indicating relatively poor discrimination; but discrimination was hampered by the fact that the risk factors are also associated with the competing risk of death.

Lifetime risk of atrial fibrillation according to levels of risk factors

Suppl. Table 8. Multivariable prediction model of the lifetime risk of atrial fibrillation at age index 55 years.

	Coef.	SE(Coef.)	Covariance	p-value
Women vs. men	-1.30439	0.31235	-0.03434	0.0000
Women vs. men x log(t)	0.31037	0.11317		0.0061
Systolic blood pressure (mm Hg)	0.00963	0.00288		0.0008
Diastolic blood pressure (mm Hg)	-0.00739	0.00520		0.1600
Treatment of hypertension	0.21862	0.08298		0.0084
Body mass index (kg/m ²)	0.07474	0.01878	-0.00012	0.0001
Body mass index x log(t)	-0.01629	0.00708		0.0210
Past smoker vs. never smoker	0.36787	0.29734	-0.03097	0.2200
Past smoker vs. never smoker x log(t)	-0.12982	0.10857		0.2300
Current smoker vs. never smoker	0.91243	0.31326	-0.03393	0.0036
Current smoker vs. never smoker x log(t)	-0.33899	0.11352		0.0028
Borderline diabetes vs. optimal diabetes	-0.12940	0.09926		0.1900
Elevated diabetes vs. optimal diabetes	-0.03556	0.13884		0.8000
History of MI or HF	1.77197	0.26611	-0.02520	0.0000
History of MI or HF x log(t)	-0.62349	0.11017		0.0000
Elevated alcohol vs. optimal alcohol	0.25184	0.08103		0.0019

We entered the 9 covariates in the model and we did not perform any variable selection.

Coef.: coefficient; SE(Coef): standard error of the coefficient. log(t): natural logarithm of time (years since index age 55 years).

The subdistribution hazard ratio is $\exp(\text{Coef})$ and the associated 95% confidence interval is from $\exp[\text{Coef}-1.96*\text{SE}(\text{Coef})]$ to $\exp[\text{Coef}+1.96*\text{SE}(\text{Coef})]$.

For sex, BMI, smoking, and history of myocardial infarction or heart failure, one needs to account for the interaction between the covariate Z and log(t). Let us note Coef1 is the coefficient for Z and Coef2 is the coefficient for the interaction between Z and log(t). The subdistribution hazard ratio is $\exp(\text{Coef1})t^{\text{Coef2}}$. The 95% confidence interval is from $\exp[\text{Coef1}+\text{Coef2} \times \log(t)-1.96*\text{SE}\{\text{Coef1}+\text{Coef2} \times \log(t)\}]$ to $\exp[\text{Coef1}+\text{Coef2} \times \log(t)+1.96*\text{SE}(\text{Coef1}+\text{Coef2} \times \log(t))]$. The standard error is $\text{SE}\{\text{Coef1}+\text{Coef2} \times \log(t)\}=\text{sqrt}[\text{SE}(\text{Coef1})^2 + \log(t)^2 \text{SE}(\text{Coef2})^2 + 2 \log(t) \text{Covariance}(\text{Coef1},\text{Coef2})]$

Lifetime risk of atrial fibrillation according to levels of risk factors

Suppl. Table 9. Lifetime risk AF by single risk factor, unadjusted for the competing risk of death.

Risk factor	Risk factor	Index age 55 years		Index age 65 years		Index age 75 years	
		AF cases/total	Lifetime risk (95%CI)	AF cases/total	Lifetime risk (95%CI)	AF cases/total	Lifetime risk (95%CI)
Smoking	Optimal	249/1935	56.4 (45.3-67.6)	316/1570	47.4 (42.1-52.6)	294/1233	42.3 (37.8-46.7)
	Borderline	343/2275	54.3 (46.6-61.9)	525/2414	53.2 (48.4-57.9)	410/1667	49.5 (45.0-54.0)
	Elevated	224/1128	59.5 (48.6-70.3)	182/821	61.4 (52.0-70.7)	72/299	54.4 (42.1-66.7)
Alcohol	Optimal	600/4283	50.9 (45.3-56.4)	799/3857	50.2 (46.6-53.7)	671/2767	46.2 (43.0-49.4)
	Elevated	216/1055	74.3 (60.5-88.0)	224/948	61.1 (52.6-69.6)	105/432	49.2 (40.3-58.2)
Body mass index	Optimal	236/1785	49.6 (40.7-58.7)	314/1537	45.7 (40.8-50.6)	255/1126	41.9 (37.0-46.9)
	Borderline	343/2136	60.6 (49.4-71.9)	422/2008	53.5 (48.1-58.9)	319/1364	47.2 (42.4-52.0)
	Elevated	237/1417	66.7 (54.4-79.1)	287/1260	61.5 (54.0-69.1)	202/709	53.3 (46.9-59.8)
Blood pressure	Optimal	152/1539	38.4 (30.0-46.8)	118/778	38.1 (30.7-45.5)	45/272	34.0 (24.0-43.9)
	Borderline	272/1792	58.5 (47.6-69.5)	254/1303	45.0 (39.5-50.4)	140/675	37.8 (31.9-43.7)
	Elevated	392/2007	66.5 (56.7-76.2)	651/2724	60.7 (55.9-65.4)	591/2252	50.8 (47.1-54.6)
Diabetes	Optimal	624/3805	56.6 (50.0-63.2)	726/3137	51.1 (47.5-54.6)	580/2249	45.7 (42.4-49.1)
	Borderline	128/1187	53.4 (26.2-80.6)	171/1149	48.1 (34.3-61.8)	110/584	48.2 (32.8-63.7)
	Elevated	64/346	53.4 (40.6-66.1)	126/519	60.9 (44.9-76.9)	86/366	53.2 (40.8-65.7)
History of heart failure or myocardial infarction	Optimal	747/5069	56.9 (50.4-63.5)	864/4236	50.9 (47.5-54.4)	607/2623	44.1 (40.8-47.4)
	Elevated	69/269	57.4 (41.5-73.3)	159/569	61.6 (51.2-72.0)	169/576	60.7 (52.1-69.4)

These results do not account for competing risk of death and overestimates the lifetime risk of atrial fibrillation.

Lifetime risk of atrial fibrillation according to levels of risk factors

Lifetime risk of atrial fibrillation according to levels of risk factors

Suppl. Table 10. Lifetime risk of atrial fibrillation at index age 55 years according to burden of risk factors with multiple imputation.

Analysis	Risk category	Men	Women
		Lifetime risk (95%CI)	Lifetime risk (95%CI)
Multiple imputation	Optimal	31.6 (10.3-52.8)	23.9 (12.0-35.9)
	Borderline	36.0 (29.8-42.2)	30.0 (24.4-35.7)
	Elevated	39.2 (36.4-42.0)	31.1 (28.3-33.8)
Complete case	Optimal	29.8 (9.7-49.9)	20.5 (7.3-33.7)
	Borderline	39.7 (31.7-47.7)	28.0 (20.6-35.4)
	Elevated	43.3 (38.4-46.2)	34.6 (30.3-39.0)

In the multiple imputation analysis, we included 6778 participants among which 1201 developed atrial fibrillation during follow-up. The mean percentage of individuals belonging to optimal, borderline, and elevated groups were 4.1%, 24.7%, and 71.2% respectively across 25 imputed datasets. Among those 6778 participants, 5338 participants (489 AF cases) didn't have any missing data for the risk factors and were included in the complete case analysis.

Lifetime risk of atrial fibrillation according to levels of risk factors

Suppl. Table 11. Lifetime risk of atrial fibrillation by BMI adjusted for the competing risk of death excluding underweighted individuals.

Risk Factor		Index age 55 years		Index age 65 years		Index age 75 years	
		AF cases/total	Lifetime risk (95%CI)	AF cases/total	Lifetime risk (95%CI)	AF cases/total	Lifetime risk (95%CI)
Body mass index	Optimal	233/1751	31.8 (27.7-36.0)	309/1493	30.3 (27.3-33.3)	247/1082	27.4 (24.4-30.5)
	Borderline	343/2136	38.2 (34.0-42.4)	422/2008	33.3 (30.5-36.1)	319/1364	30.1 (27.2-33.0)
	Elevated	237/1417	44.2 (38.5-50.0)	287/1260	40.7 (36.7-44.8)	202/709	38.7 (34.2-43.2)

The number of underweighted (BMI<18.5 kg/m²) individuals excluded from the optimal category were 34, 44, and 44 for index age 55 years, index age 65 years, and index age 75 years respectively.
