## Table of contents:

Supplementary Methods.....	S2
VT NMR and NMR dilution studies .....	S3
Chirality induction experiments .....	S5
DFT Calculations .....	S7
PSS determination by <sup>1</sup> H NMR.....	S19
Quantum yield determination.....	S21
<sup>1</sup> H, <sup>13</sup> C and <sup>31</sup> P NMR Spectra.....	S24
Supplementary References .....	S32

## Supplementary Methods

### General methods and materials:

THF and CH<sub>2</sub>Cl<sub>2</sub> were dried by using an MBraun solvent purification system. Anhydrous MeOH and pyridine were purchased from Acros Organics. The degassing of solvents was carried out by purging with Argon for at least 30 min. Tetrabutylammonium hydroxide-30 hydrate and phosphoryl chloride were purchased from Sigma-Aldrich and the enantiomers (*S*)- and (*R*)- 5,5',6,6',7,7',8,8'-octahydro-1,1'-bi-2-naphthol were obtained from TCI. The isomers (*E*)- and (*Z*)-2,2',3,3'-tetrahydro-(1,1'-biindenylidene)-6,6'-diamine were prepared according to a procedure described in the literature.<sup>1</sup> All other chemicals were commercial products and were used as received. Flash chromatography (FC) was performed using silica gel (SiO<sub>2</sub>) purchased from Machery-Nagel (0.04-0.063 mm) and thin-layer chromatography (TLC) was carried out on aluminium sheets coated with silica 60 F254 obtained from Merck; compounds were visualized with a UV lamp (254 nm). Melting points (m.p.) were determined using a Büchi-B545 capillary melting point apparatus. <sup>1</sup>H, <sup>13</sup>C and <sup>31</sup>P NMR spectra were recorded on Varian Mercury Plus-400, Agilent 400-MR, Varian Unity Plus-500 and Varian Inova-600 spectrometers at 298K unless indicated otherwise. Chemical shifts ( $\delta$ ) are denoted in parts per million (ppm) relative to CD<sub>2</sub>Cl<sub>2</sub> (for <sup>1</sup>H detection,  $\delta$  = 5.32 ppm; for <sup>13</sup>C detection,  $\delta$  = 53.84 ppm), DMSO-*d*<sub>6</sub> (for <sup>1</sup>H detection,  $\delta$  = 2.50 ppm; for <sup>13</sup>C detection,  $\delta$  = 39.52 ppm) or aqueous 85% H<sub>3</sub>PO<sub>4</sub> (for <sup>31</sup>P detection,  $\delta$  = 0.00 ppm). The splitting pattern of peaks is designated as follows: s (singlet), d (doublet), t (triplet), (multiplet), br (broad), or dd (doublet of doublets). High-resolution mass spectrometry (ESI-MS) was performed on a LTQ Orbitrap XL spectrometer with ESI ionisation. UV-vis spectra were recorded on a HP 8543 diode array spectrophotometer, equipped with a Quantum Northwest Peltier controller, in a 1 cm or 1 mm quartz cuvette. CD spectra were measured on a Jasco 810-CD instrument.

## VT NMR and NMR dilution studies

**Supplementary Figure 1.** Aromatic and aliphatic region in the <sup>1</sup>H NMR spectrum of (Z)-2 (2 mM in CD<sub>2</sub>Cl<sub>2</sub>) before (top, 400 MHz) and after addition of 1 equivalent of [Bu<sub>4</sub>N]<sup>+</sup>[(S)-3]<sup>-</sup> (below, 500 MHz). The <sup>1</sup>H NMR spectrum of the mixture was recorded at various temperatures ranging from 25 °C to -65 °C. Assignments are based on COSY and NOESY spectra.

**Supplementary Figure 2.** Aromatic and aliphatic region in the <sup>1</sup>H NMR spectrum (400 MHz) of (Z)-2 in CD<sub>2</sub>Cl<sub>2</sub> at different concentrations ranging from 10 to 0.5 mM.

## Chirality induction experiments

**Supplementary Figure 3.** CD (top) and UV-vis (bottom) absorption spectra of  $[Bu_4N]^+[(S)-3]^-$  (CD; red line) and  $[Bu_4N]^+[(R)-3]^-$  (CD; blue line) in  $CH_2Cl_2$  ( $c = 5.0 \times 10^{-4}$  M, 25 °C, 1 mm quartz cuvette).

**Supplementary Figure 4.** CD (top) and UV-vis (bottom) spectral changes upon stepwise addition of  $[\text{Bu}_4\text{N}]^+[(S)\text{-3}]^-$  (0.0, 0.2, 0.5, 1.0, 2.0 and 4.0 equiv.) to  $(E)\text{-2}$  in  $\text{CH}_2\text{Cl}_2$  ( $c = 5.0 \times 10^{-4}$  M, 25 °C, 1 mm quartz cuvette).

## DFT Calculations

The Gaussian 09 program<sup>2</sup> was used for geometry optimisations, calculation of energies and time-dependent DFT calculations. Initially different input geometries were optimised at the semi-empirical PM6 level to find the global minima.

**Geometry optimisation and energy barrier for helicity inversion of stiff-stilbene.** The geometries of the (*E*)-, (*P*)-(*Z*)- and (*M*)-(*Z*)-isomer (Supplementary Fig. 5) were optimised first at the PM6 level and a transition state was found by a central dihedral scan. Additional optimisation and frequency analysis were performed on the DFT B3LYP/6-31G+(d,p) level of theory using tight convergence criteria. The DFT-optimized structures were found to have zero imaginary frequencies, except for the transition state, which had one imaginary frequency;  $\Delta^\ddagger G_{298} = 16.7 \text{ kJ mol}^{-1}$ . Cartesian coordinates are given in Supplementary Table 1-4.

**Supplementary Figure 5.** Line drawings of the (*E*)- and (*Z*)-isomer of stiff-stilbene, showing the possible (*P*)- and (*M*)-helical conformations for the latter.

**Geometry optimisation of (*P*)-(*Z*)-2@(*S*)-3 and (*M*)-(*Z*)-2@(*S*)-3.** Two conformations of the octahydro-1,1'-bi-2-naphthol unit, both found in reported solid state structures,<sup>3</sup> were considered. In one conformation the hydrogen atoms in the 8,8'-positions point toward each other ( $H_{in}$ ), while in the other they point away from each other ( $H_{out}$ , see Supplementary Fig. 6). Structures with  $H_{in}$  were found to be the lowest in energy on the PM6 level. Further geometry optimisation, frequency analysis and time-dependent DFT calculations were performed on the DFT B3LYP/6-31G++(d,p) level of theory using tight convergence criteria and an IEFPCM  $\text{CH}_2\text{Cl}_2$  solvation model. The DFT-optimized structures were found to have zero imaginary frequencies. Cartesian coordinates are given in Supplementary Table 5-6.

**Supplementary Figure 6.** Possible conformations of (*S*)-5,5',6,6',7,7',8,8'-octahydro-1,10-binaphthyl-2,2'-diyl phosphate considered in the DFT geometry optimisations.

**Supplementary Figure 7.** Experimental (red, solid) and calculated (blue, dashed) CD spectra of (*P*)-(*Z*)-**2**@(*S*)-**3** (30 electronic transitions were computed). Intensities were normalised and the calculated spectrum was blue-shifted by 18 nm for easier comparison.

**Supplementary Table 1.** Cartesian coordinates of (*E*)-stiff-stilbene.

## PSS determination by $^1\text{H}$ NMR

**Supplementary Figure 8.** (top) Aromatic and aliphatic region in the  $^1\text{H}$  NMR spectrum (600 MHz) of  $(E)\text{-2}$  (2 mM) in degassed  $\text{CD}_2\text{Cl}_2$ . (below) Spectral changes upon irradiation with 365 nm light. The PSS  $E/Z$  ratio (42:58) was determined by integration of the  $\text{CH}_2$  signals.

**Supplementary Figure 9.** (top) Aromatic and aliphatic region in the  $^1\text{H}$  NMR spectrum (600 MHz) of a 1:1 mixture of  $(E)\text{-2}$  and  $[\text{NBu}_4]^+[(S)\text{-3}]^-$  (2 mM) in degassed  $\text{CD}_2\text{Cl}_2$ . (below) Spectral changes upon irradiation with 365 nm light. The PSS  $E/Z$  ratio (24:76) was determined by integration of the  $\text{CH}_2$  signals.

## Quantum yield determination

An aqueous 0.05 M H<sub>2</sub>SO<sub>4</sub> solution containing 6 mM potassium ferrioxalate (2 mL, 1 cm quartz cuvette) was irradiated at 20 °C for 30, 60, 90, 120 or 150 s in the dark with the Thorlab model F365F1 high-power LED ( $\lambda_{\text{max}} = 365$  nm). A volume of 1 mL was taken and diluted 3× with an aqueous 0.5 M H<sub>2</sub>SO<sub>4</sub> solution containing phenanthroline (0.1 wt%). The absorption at  $\lambda = 510$  nm was measured and compared to an identically prepared non-irradiated sample. The concentration of [Fe(phenanthroline)<sub>3</sub>]<sup>2+</sup> complex was calculated using its molar absorptivity ( $\varepsilon = 11100 \text{ m}^{-1} \text{ cm}^{-1}$ ). This concentration corresponded to  $\frac{1}{3}$  (cf. 3× diluted) of the concentration of Fe<sup>2+</sup> ions that had formed upon irradiation. The Fe<sup>2+</sup> ion concentration was plotted versus time and the slope, obtained by linear fitting to the equation  $y = ax + b$  using Origin software (Supplementary Fig. 10), equals the rate of formation.

Solutions of (*E*)-**2** in the absence and presence of 1 equiv. of [NBu<sub>4</sub>]<sup>+</sup>[(*S*)-**3**]<sup>-</sup> were irradiated with the Thorlab model F365F1 high-power LED under identical conditions at concentrations high enough to absorb all incident light ( $\text{Abs}_{365} \geq 2$ ). The absorbance increase was monitored over time by UV-vis spectroscopy. The molar absorptivities at  $\lambda = 380$  nm [i.e. for (*E*)-**2**,  $\varepsilon = 618 \text{ M}^{-1} \text{ cm}^{-1}$ ; for (*Z*)-**2**,  $\varepsilon = 3505 \text{ M}^{-1} \text{ cm}^{-1}$ ; for (*E*)-**2**@**3**,  $\varepsilon = 1311 \text{ M}^{-1} \text{ cm}^{-1}$ , for (*Z*)-**2**@**3**,  $\varepsilon = 5030 \text{ M}^{-1} \text{ cm}^{-1}$ ] were used to calculate the concentration increase of (*Z*)-**2** according to  $\Delta c = \Delta \text{abs} / \varepsilon_{\text{E}} + \varepsilon_{\text{Z}}$ . The initial concentration increase was plotted versus time (Supplementary Figs. 12 and 13) and the slope, representing the rate of formation, was obtained by linear fitting to the equation  $y = ax + b$  using Origin software. The photochemical quantum yield was calculated by comparison of the rate of formation of (*Z*)-**2** with the rate of Fe<sup>2+</sup> ion formation from potassium ferrioxalate using the known quantum yield for the latter process ( $\Phi = 1.21$ ).<sup>4</sup>

**Supplementary Figure 10.** Concentration of  $\text{Fe}^{2+}$  ions measured after five different irradiation times (30, 60, 90, 120, 150 s). The slope of the plot corresponds to the rate of  $\text{Fe}^{2+}$  ion formation:  $5.87 \times 10^{-7} \text{ M s}^{-1} \pm 4.62 \times 10^{-8} \text{ M s}^{-1}$ .

**Supplementary Figure 11.** UV-vis spectral changes upon irradiation of a solution of (*E*)-**2** in  $\text{CH}_2\text{Cl}_2$  ( $c = 2.0 \times 10^{-4} \text{ M}$ , 1 mm quartz cuvette) with  $\lambda_{\text{max}} = 365 \text{ nm}$  light.

**Supplementary Figure 12.** Plot of the concentration of (Z)-2 as a function of time during  $\lambda_{\max} = 365$  nm irradiation of a solution of (E)-2 in  $\text{CH}_2\text{Cl}_2$  ( $c = 3.0 \times 10^{-4}$  M, 1 cm quartz cuvette) obtained by monitoring the absorption increase at  $\lambda = 380$  nm. The slope of the plot corresponds to the  $E \rightarrow Z$  isomerisation rate:  $8.83 \times 10^{-8} \text{ M s}^{-1} \pm 1.54 \times 10^{-9} \text{ M s}^{-1}$ .

**Supplementary Figure 13.** Plot of the concentration of (Z)-2 as a function of time during  $\lambda_{\max} = 365$  nm irradiation of a mixture of (E)-2 and  $[\text{NBu}_4]^+[(\text{S})\text{-3}]^-$  in  $\text{CH}_2\text{Cl}_2$  ( $c = 2.0 \times 10^{-4}$  M, 1 cm quartz cuvette) obtained by monitoring the absorption increase at  $\lambda = 380$  nm. The slope of the plot corresponds to the  $E \rightarrow Z$  isomerisation rate:  $9.75 \times 10^{-8} \text{ M s}^{-1} \pm 1.72 \times 10^{-9} \text{ M s}^{-1}$ .
