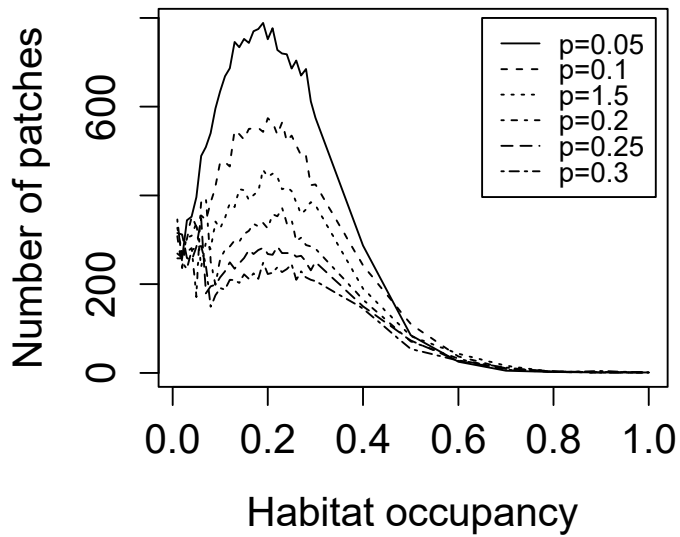

Figure S1. Relations between Modified Random Clusters parameters (habitat occupancy and percolation probability) and traditional fragmentation statistics in simulated landscapes. **(a)** Patch isolation as a function of habitat occupancy A . **(b)** Patch isolation as a function of percolation probability p . **(c)** Mean patch area as a function of A . **(d)** Mean patch area as a function of p . **(e)** Number of patches as a function of p . **(f)** Number of patches as a function of A .

Figure S2. Predicted LD risk of simulated landscapes (excluding one-cell forest patches) as a function of habitat occupancy (forest cover). Each curve is evaluated for a landscape with a different percolation probability p .

Figure S3. Predicted LD risk as a function of number of forest patches.

Figure S4. Frequency distribution of log-transformed deciduous and mixed forest patch areas.

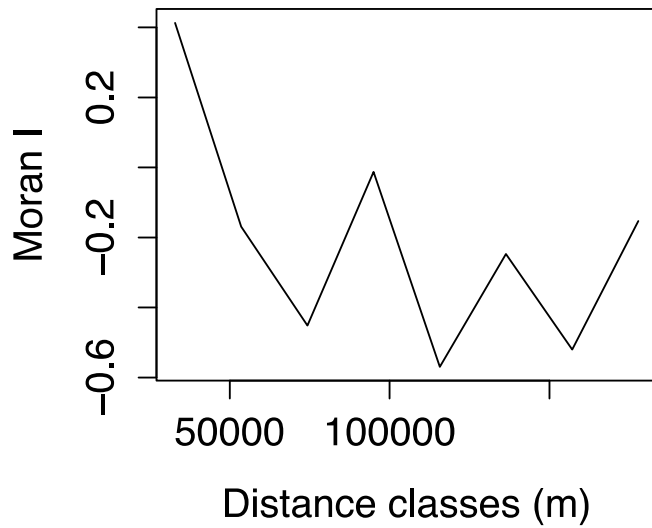

Figure S5. Lyme disease incidence (LDI) correlogram. Plot of Moran's I for LDI as a function of distance class within study region.
