*Bold type shows statistically significant result based on p-value.[†]Defined from computerized pharmacy data as filling ≥ 2 prescriptions (in what time period? Ever?).

[‡]Defined from pharmacy data as having a fill within the prior 30 days. ^xHRs and corresponding 95% CIs from splines are non-interpretable and therefore are not presented here. To illustrate the pattern of risk based on age, we have calculated the HR of fracture comparing those who are 90 vs 65 years of age and those who are 80 vs 65 years of age keeping all other covariates constant. Holding all other covariates constant, 90 year olds have a 3.2 (95% CI: 0.70-14.73) times greater hazard of fracture than those who are 65 and 80 year olds have a 1.57 (95% CI: 0.78-3.15) times greater hazard of fracture than those who are 65.
