I. Country selection and Demographic and Health Survey year

We selected 41 low- and middle-income countries with Demographic and Health Surveys available after 2010, listed in Table S1 (1).

Table S1. List of 41 countries and Demographic and Health Survey year

Country	Year of Demographic and Health Survey
Armenia	2010
Bangladesh	2011

II. Methods in detail

- a. An example of the method to distribute cases/deaths across wealth quintiles

We estimate the distribution of cases when no vaccines are available based on two inputs: the relative risk of the risk factor (how important the risk factor is in increasing the likelihood of the disease) and the prevalence of the risk factor (how common it is in each quintile).

As an example, assume we have three risk factors, A, B, and C for measles, and the relative risk of each are 5.0, 3.0, and 2.0. Following the equation $w_j = \frac{RR_j}{\sum_{k=1}^n RR_k}$, the weight we assign for each risk factor would be:

$$w_a = \frac{5.0}{(5.0 + 3.0 + 2.0)} = 0.5$$

$$w_b = \frac{3.0}{(5.0 + 3.0 + 2.0)} = 0.3$$

$$w_c = \frac{2.0}{(5.0 + 3.0 + 2.0)} = 0.2$$

Second, assume we know from the DHS that the prevalence of risk factor A for each quintile is 90%, 80%, 70%, 60%, and 50%, for risk factor B is 50%, 40%, 30%, 20%, 10%, and for risk factor C is 5%, 4%, 3%, 2%, 1%.

Then, following equation (1) from the main text $A_{C_i} = \frac{\sum_{j=1}^n w_j P_{ij}}{\sum_{m=1}^5 \sum_{j=1}^n w_j P_{mj}}$, the proportion of attributable cases occurring in the first quintile would be:

$$\frac{(weight\ of\ A * prevalence\ of\ A\ in\ quintile\ 1 + weight\ of\ B * prevalence\ of\ B\ in\ quintile\ 1 + weight\ of\ C * prevalence\ of\ C\ in\ quintile\ 1)}{\text{sum of the products of weight and prevalence of all quintiles}}$$

With this example, it would be:

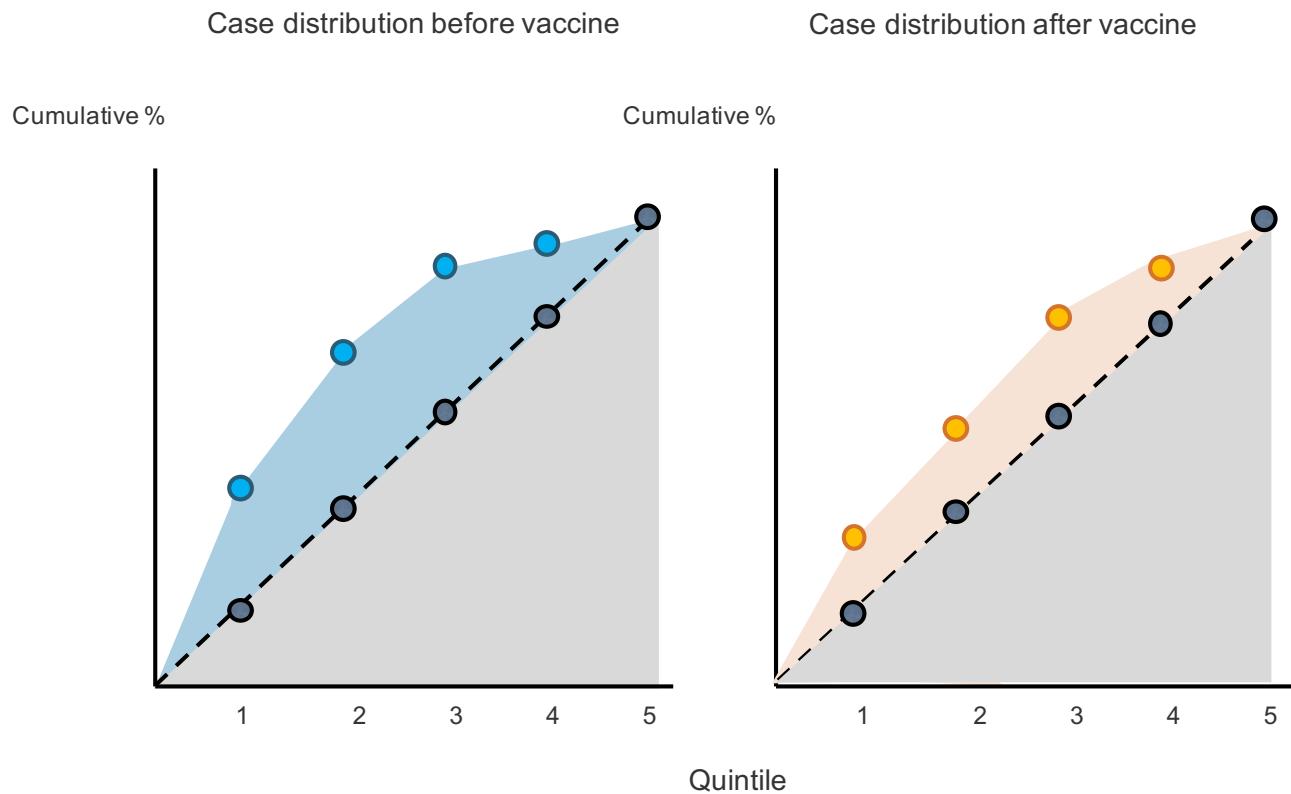

$$\frac{(0.5 * 90\% + 0.3 * 50\% + 0.2 * 5\%)}{(0.5 * (90\% + 80\% + 70\% + 60\% + 50\%) + 0.3 * (50\% + 40\% + 30\% + 20\% + 10\%) + 0.2 * (5\% + 4\% + 3\% + 2\% + 1\%)} = 27\%$$

We interpret this to say that, out of the 100% of cases that would happen in this country, we expect to have 27% of cases in quintile 1.

b. Calculation of the area under the curve (AUC)

To compare the distributions of cases (or deaths) in each of the scenarios, we explored the area under the curve (AUC) of the cumulative percentage of cases (or deaths) by quintile, and calculated the changes in the AUC for each scenario, compared to Scenario 1 when no vaccines (or treatment) are available. For example, an increase in the AUC after vaccine program suggests that, among the remaining cases not averted by the program, a higher percentage of cases would be among the lower wealth quintiles compared to prior vaccine program. As illustrated in Figure S3.1, if cases are distributed equally across quintiles (i.e., 20% in each quintile), the AUC equals 250 ($=5*100/2$). Having an AUC greater than 250 (the area outside of the triangle) suggests that higher percentages of cases are in the lower wealth quintiles. The illustration shows a decrease in AUC after vaccine introduction (decrease in the area). On the other hand, an increase in the AUC between the two scenarios suggests that, among the remaining cases not averted by the program, a higher percentage of cases is among the lower wealth quintiles compared to prior vaccine introduction.

Figure S3.1. Illustration of the area under the curve analysis.

III. Selection of risk and prognostic factors

We first searched the literature for risk and prognostic factors with the highest relative risks for diarrhea, measles, and pneumonia. For each risk factor, we also checked its availability by quintile-specific prevalence rate in the DHS (1). Factors that did not match with DHS variables, had poor data quality, were not studied in systematic reviews, or had poor variable definition according to experts were excluded. We shortlisted five factors per disease (listed in the main paper, Table 2).

Prevalence rates by wealth quintile for malnutrition metrics (wasting, underweight, and stunting) and low birth weight were available in the DHS for most countries. The relative risk (RR) for each childhood malnutrition exposure is adjusted for the joint effect of the other malnutrition indicators, as described by the GBD 2013 Risk Factors Collaborators (2), and therefore assumed independent. We applied neighboring country data to countries with missing data.

Prevalence rates of vitamin A deficiency by wealth quintile were proxied with the percentage not given vitamin A supplements in the past six months among children aged 6 to 59 months. For countries missing this variable, we used the percentage who did not consume foods rich in vitamin A in the past 24 hours among age 6 to 23 months as replacement.

For estimating the level of sanitation in one's household, we used the percentage of children whose stools were not disposed safely as a proxy.

For non-exclusive breastfeeding, the DHS provides data on the median duration (in months) of exclusive breastfeeding in the past three years by wealth quintile, and the national average (percentage) of exclusive breastfeeding among children of ages zero to five months and zero to six months. To estimate the burden of non-exclusive breastfeeding, we assumed that the ratio of the average duration of exclusive breastfeeding of a wealth quintile to the national average is proportional to the ratio of the percentage of people exclusively breastfeeding in the same wealth quintile to the national average. The burden of non-exclusive breastfeeding is calculated as 100% minus the estimated prevalence of exclusive breastfeeding.

IV. Input data

Table S4.1. Input data for quintile-specific vaccine and treatment coverage rates, risk and prognostic factor prevalence, and total fertility rate for 41 low- and middle-income countries.

Country	Quintile	MCV cover age	DPT2 cover age	DPT3 cover age	Among children under 5 with fever, percentage for whom advice or treatment was sought from a health facility or provider	Among children under 5 with acute respiratory infection, percentage for whom advice or treatment was sought from a health facility or provider	Percentage of children with diarrhoea for whom advice or treatment was sought from a health facility or provider	Weight-for-height (wasting) z-score < -3SD	Weight-for-age (underweight) z-score < -3SD	Height-per-age (stunting) z-score < -3SD

V. Full results

Table S5.1-S5.6 show the full results from the analysis for all 41 countries. For each scenario, we report the total number of cases/deaths averted (expressed as a percentage decrease) from Scenario 1, and the change in the area under the curve (expressed as a percentage) from Scenario 1.

The definitions of the five scenarios for the cases and deaths are:

Cases

- S1: distribution of cases when no vaccine is available;
- S2: current quintile-specific vaccine coverage rates;
- S3: national average of vaccine coverage for all quintiles;
- S4: vaccine coverage proportional to quintile-specific baseline mortality risks;
- S5: equal baseline morbidity risk with current quintile-specific vaccine coverage rates.

Deaths

- S1: distribution of deaths when no treatment is available;
- S2: current quintile-specific treatment coverage rates;
- S3: national average of treatment coverage for all quintiles;
- S4: treatment coverage proportional to quintile-specific baseline mortality risks;
- S5: equal baseline mortality risk with current quintile-specific treatment coverage rates.

Table S5.1. Change in the distribution of measles cases by wealth quintile for four scenarios, compared to when no vaccines are available (Scenario 1).

Country	Total cases averted (%)				Change in AUC (compared to S1) (%)			
	S2	S3	S4	S5	S2 AUC	S3 AUC	S4 AUC	S5 AUC
Armenia	82.4 (80.3, 84.4)	78.4 (76.4, 80.4)	79.2 (76.8, 81.7)	82.3 (80.3, 84.3)	-3.0 (-3.4, -2.6)	17.7 (15.9, 19.9)	-14.9 (-17.6, -12.4)	-11.2 (-12.1, -10.1)
Burundi	80.6 (78.5, 82.6)	78.0 (76.0, 80.0)	79.3 (77.1, 81.5)	80.8 (78.8, 82.7)	4.0 (3.5, 4.5)	14.4 (12.9, 16.1)	-15.5 (-18.5, -12.2)	-2.7 (-4.3, -1.0)
Benin	54.2 (52.2, 56.2)	54.2 (52.3, 56.2)	56.3 (54.9, 57.7)	55.3 (53.9, 56.6)	9.9 (9.3, 10.4)	7.7 (7.3, 8.1)	-8.2 (-9.2, -7.2)	3.7 (3.0, 4.3)

VI. Sensitivity analyses

We performed two sets of sensitivity analyses.

1. Sensitivity analysis 1. *Accounting for differences in the sizes of the under-five population in each quintile applying a total fertility rate adjustment*

First, we accounted for the differences in the sizes of the under-five population in each quintile by adjusting the number of cases and deaths with the quintile-specific total fertility rate (TFR):

$$C_i = [Ac_i \times TC_a + UAc_i \times TC_{ua}] \times \frac{TFR_i}{TFR_{avg}} ,$$

$$D_i = [Ad_i \times TD_a + UAd_i \times TD_{ua}] \times \frac{TFR_i}{TFR_{avg}} .$$

where TFR_i and TFR_{avg} are the quintile-specific and national average of TFR, respectively.

Higher TFR in lower wealth quintiles leads to greater number of susceptible children and therefore larger proportions of cases and deaths in these quintiles. We present the full results of the sensitivity analysis for cases and deaths in Tables S6.1 and S6.2, respectively. We highlighted the results with significant differences in the change in the AUC of greater than 25% compared to the main results (presented in Appendix V).

We found that the results were mostly sensitive to this adjustment, mainly because the TFR adjustment makes the underlying distribution of cases and deaths more unequal (more cases and deaths occur in the lower wealth quintiles), and therefore increases the effect of the vaccine/treatment scenarios on the distribution. As expected, the changes in the AUC for all scenarios are more favorable (more equal distribution of cases and deaths) than the main results. We therefore conclude that our main results (presented in the main text and Appendix V) that did not reflect the TFR adjustment are conservative estimates of the effect of vaccines and treatment on the distributions of disease cases and deaths.

2. Sensitivity analysis 2. *Replacing the flat distribution of the unattributable cases and deaths with a distribution comparable to the distribution of quintile-specific under-five mortality rates.*

Instead of assuming that unattributable cases and deaths (UAc_i and UAd_i) follow a flat distribution, we replaced it with the ratios of under-five mortality rates from each quintile ($U5M_i$) to check the impact of this assumption on our results:

$$UAc_i = UAd_i = \frac{U5M_i}{\sum_{j=1}^5 U5M_j} .$$

In all countries, U5M in the lower wealth quintiles are greater than in the higher wealth quintiles, therefore replacing the flat distribution with U5M would lead to greater differences in the distribution of cases and deaths across quintiles. On average, the proportion of unattributable cases/deaths are 27%/28% for measles, 10%/7% for pneumonia, and 5%/4% for diarrhea. The impact of this replacement should be greater on countries with higher proportion of unattributable cases/deaths.

In Tables S6.3 and S6.4 we highlight the results with significant differences in the change in AUC of greater than 25% for cases and deaths, respectively, compared to the main results (presented in Appendix V). We found that the results were mostly not sensitive to this adjustment. The results that had larger differences compared to the main results were for Scenario 5 of PCV and RV. This scenario assumes equal baseline mortality risk with current quintile-specific treatment coverage rates. In this sensitivity analysis, the change in the AUC were more favorable (more equal distribution of cases across quintiles) than the main results because countries started with more unequal case distributions, and therefore the lower quintiles benefited more when baseline mortality risk was equalized.

Table S6.1. Sensitivity analysis – change in the area under the curve (AUC) for cases, compared to Scenario 1, with total fertility rate adjustment. Highlighted cells represent greater than 25% difference compared to the main results in Appendix V.

Scenarios:

S2: current quintile-specific vaccine coverage rates;

S3: national average of vaccine coverage for all quintiles;

S4: vaccine coverage proportional to quintile-specific baseline mortality risks;

S5: equal baseline morbidity risk with current quintile-specific vaccine coverage rates.

Table S6.2. Sensitivity analysis – change in the area under the curve (AUC) for deaths, compared to Scenario 1, with total fertility rate adjustment. Highlighted cells represent greater than 25% difference compared to the main results in Appendix V.

Scenarios

S2: current quintile-specific treatment coverage rates;

S3: national average of treatment coverage for all quintiles;

S4: treatment coverage proportional to quintile-specific baseline mortality risks;

S5: equal baseline mortality risk with current quintile-specific treatment coverage rates.

N/A: estimates not available due to no vaccine introduction in 2016.

Table S6.3. Sensitivity analysis – change in the area under the curve for cases, compared to Scenario 1, with under-five mortality rate adjustment. Highlighted cells represent greater than 25% difference compared to the main results in Appendix V.

Scenarios:

S2: current quintile-specific vaccine coverage rates;

S3: national average of vaccine coverage for all quintiles;

S4: vaccine coverage proportional to quintile-specific baseline mortality risks;

S5: equal baseline morbidity risk with current quintile-specific vaccine coverage rates.

N/A: estimates not available due to no vaccine introduction in 2016.

Table S6.4. Sensitivity analysis – change in the area under the curve for death, compared to Scenario 1, with under-five mortality rate adjustment. None of the cells had greater than 25% difference compared to the main results in Appendix V.

Scenarios

S2: current quintile-specific treatment coverage rates;

S3: national average of treatment coverage for all quintiles;

S4: treatment coverage proportional to quintile-specific baseline mortality risks;

S5: equal baseline mortality risk with current quintile-specific treatment coverage rates.
