

New generation sequencing of targeted genes in the classical and the variant form of hairy cell leukemia highlights mutations in epigenetic regulation genes

SUPPLEMENTARY MATERIALS

DNA and RNA purification, ARMSqPCR analysis

DNA and RNA was extracted with the automated device MagnaPur[®] (Roche Lifescience) according to the manufacturer's recommendations. Retro-transcription of RNA (SuperScript[™] II, Invitrogen) was performed using oligodT primer (Invitrogen). gDNA and cDNA quality and quantity were measured by spectrophotometry (Nanodrop 2000[®], Labtech). The presence of *BRAF^{V600E}* mutation was initially analyzed by allele specific amplification ARMSqPCR adapted from Schnittger *et al* as previously described [1].

Immunophenotyping

Multiparameter flow cytometric immunophenotype performed on a FACS CANTO II or a FACSCalibur (Becton Dickinson, (BD)) was used to characterize hairy cells (HC) and quantify tumor infiltration. PBMC (5×10^5 cells) were incubated for 30 minutes at 4° C with the following antibodies: anti-CD45-V450, -CD5-PerCpCy5,5, -CD19-PECy7, -CD23-PE, -CD43-FITC, -CD10-APC, -CD38-V450, -CD103-FITC, -CD123-PE, -CD11c-V421, -CD25-APC purchased from Becton

Dickinson or anti- κ -FITC and - λ -PE from Dako. Antibody excess was washed with the lyse/lavage BD FACS[®] device (Becton Dickinson). Devices were standardized with EuroFlow recommendation [2]. Data were analyzed using the FACSDiva software (Becton Dickinson). Cells were gated according to side scatter-CD45⁺, specific expression of CD19, CD11c \pm CD103 \pm CD123 \pm CD25 and kappa/lambda restriction for measurement of tumor infiltration.

A ChrX(GRCh37):g.44945109G>A,NM_021140.2(KDM6A):c.3434-1G>A (Intron 23)

B KDM6A

Supplementary Figure 1: Variation at 3' splice site induces skipping of KDM6A exon 24 according to RNA sequencing. (A) *In silico* prediction of splicing variation for KDM6A mutation c.3434-1G > A with Alamut® Visual 2.9 (Interactive Biosoftware), diminution of prediction score of splicing site according to the mutational status. (B) Sanger RNA sequencing of exon 23→25 of KDM6A in UPN-v1. The mutation c.3434-1G > A (orange arrow) leads to exon 24 skipping.

Supplementary Figure 3: Copy number evaluation Copy number (CN) variation was detected from exon sequencing of the target genes after normalization using ONCOCNV tools. (A–C) Log-ratio representation represent significant loss (red) and gain (blue) of copy number gene in healthy male patient (A) UPN-23 (B) and UPN-v2 (C). Statistical CNV differences was estimated with p -value of normalized read count and p values < 0.05 were considered statistically significant. (A) healthy male patient has no abnormal CNV and X monosomy was highlighted with *BCOR* and *KDM6A* loss. (B) UPN-23 have *MAPK15* loss and male phenotype (*BCOR* and *KDM6A* loss). (C) UPN-v2 have *EZH2* loss and male phenotype (*BCOR* and *KDM6A* loss). *BRAF*, *MAP2K1* and *UZAF1* CNV cannot be exploited for statistical analyze because the small number of amplicons (<5) do not allowed optimal statistical conditions.

Supplementary Table 1: Cohort data. See Supplementary_Table_1

Supplementary Table 2: Performance data of targeted sequencing

| Samples | Number of mapped reads | Reads on-target (%) | Total aligned base reads (pb) | Bases reads on target (%) | Targeted base coverage > 20 reads (%) | Targeted base coverage > 100 reads (%) | Uniformity of base coverage (%) | Mean depth (X) |
