For 10gs, 13gs, 17gs, 19gs, 1aax, 1ad5, 1ad8, 1aqw, 1aqx, 1avn, 1bb5, 1bic, 1bio, 1bpy, 1bzs, 1c5x, 1e2s, 1e7a, 1e7b, 1e7c, 1exa, 1exx, 1f5k, 1fak, 1fcx, 1fcy, 1fcz, 1fd0, 1fdt, 1fjs, 1fzc, 1g3m, 1g4k, 1g86, 1gc1, 1gni, 1gra, 1gzp, 1gzq, 1h07, 1h08x3, 1h0cx3, 1i5r, 1iei, 1ii6, 1itu, 1j78, 1jdp, 1li4, 1mc5, 1mrq, 1nrg, 1op3, and 1op3. In the case of certain proteins that bind two ligands, two pockets were prepared.

## APPENDIX B

The ChEMBL database records the affinity data ( $IC_{50}$ , %-inhibition, %-residual activity, etc.) without experimental detail parameters, which are the densities of inhibitors and ligands. We must check the references to determine these parameters, or we must use standard values instead of the actual experimental values. In the present study, we used the standard values for the densities of the inhibitors and ligands. The protein–compound binding energy  $\Delta G$  is calculated from the  $K_d$  value as follows:

$$\Delta G = k_B \cdot T \cdot \ln(K_d), \quad \text{eq. S1}$$

where  $k_B$  and  $T$  are the Boltzmann constant and temperature, respectively. In the present study, we assumed that  $K_d = K_i$ , since the binding affinities of the natural ligands have been reported to be much weaker than those of the reported artificial ligands in many proteins. In addition, the %-inhibition value ( $r$ ) gives the  $K_i$  values as follows in the present study.

$$K_i = \frac{[I]}{\frac{[S]/(1-r)-[S]}{K_s} - 1} \quad \text{eq. S2}$$

Here  $K_s$ ,  $[S]$ , and  $[I]$  are the rate constant, the density of the inhibitor, and the density of the substrate, respectively. The  $IC_{50}$  value is converted to the  $K_i$  value by the Cheng–Prusoff equation as follows.<sup>[32, 49]</sup>

$$K_i = \frac{IC_{50}}{1 + \frac{[S]}{K_s}} \quad \text{eq. S3}$$

As shown above, the  $\Delta G$  value depends on the densities of the inhibitor, substrate, and  $K_s$ . The ChEMBL database does not provide these parameters explicitly. Instead of the true parameters described in each original experimental article, we used the same set of standard values for these parameters that we used in our previous work. Namely,  $[I] = 50 \mu\text{M}$ ,  $[S] = 20 \mu\text{M}$ , and  $K_s = 1 \mu\text{M}$  in both eqs. S2 and S3, and  $[S]/K_s = 1$  in eq. S3.

Assay data with inadequate energy units or unclear energy values were excluded. The assay data for large compounds (mass weight > 500 Da) and very small compounds (mass weight < 150 Da) were also excluded, since Sievgene is designed for the docking of small compounds with mass weights > 150 Da and mass weights < 500 Da. In addition, we avoided the chemical compound structures that were not consistent with the same compounds registered in the PubChem database.

**Table S5.**  $Q^2$  values for selected kinases. The docking-score QSAR method (4-fold cross validation tests) and the myPresto/sievgene docking program with using the default parameters give the  $Q^2$  and RMSEP values.

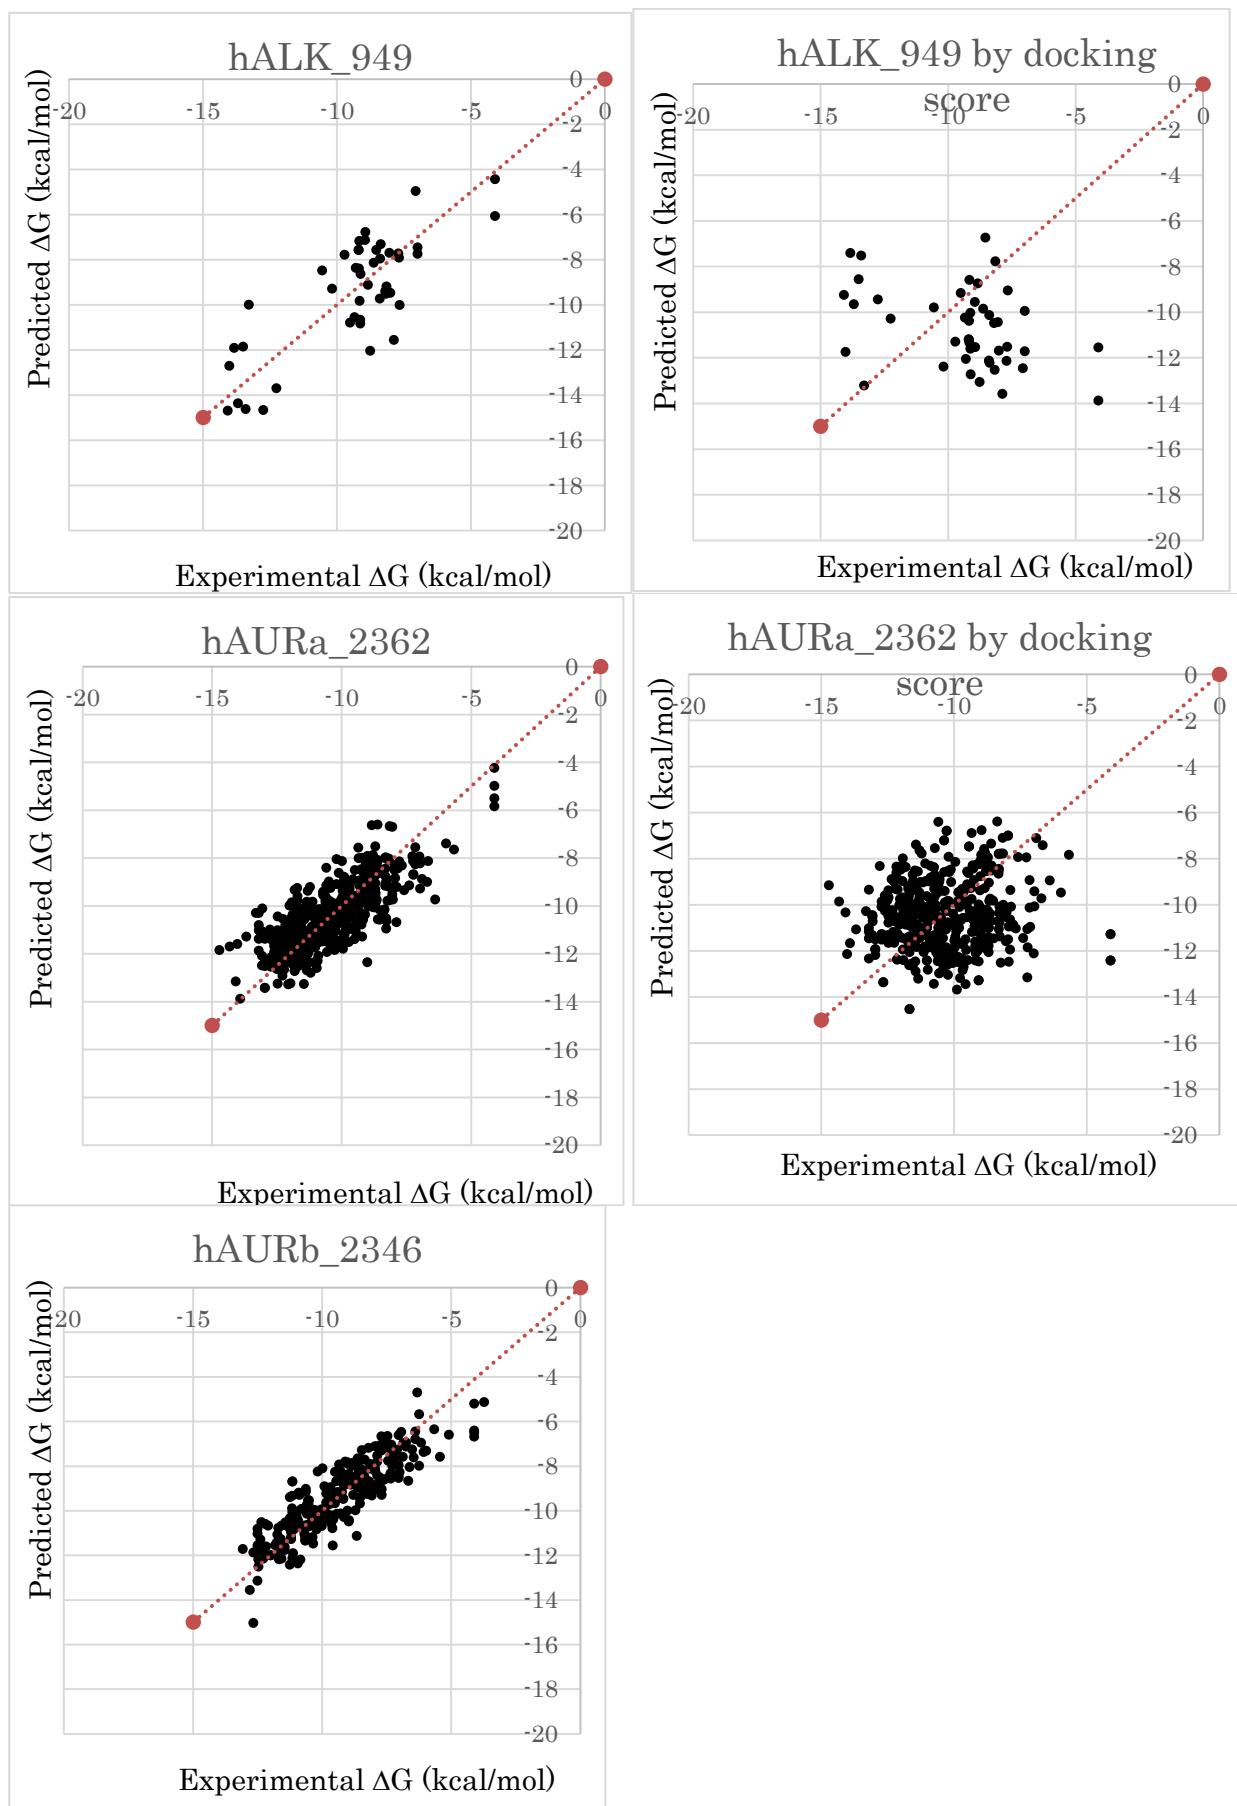

**Figure S1** W dependence of  $Q^2$  and RMSEP. Blue and orange lines represent  $\lambda=0.002$  and  $0.005$ , respectively.

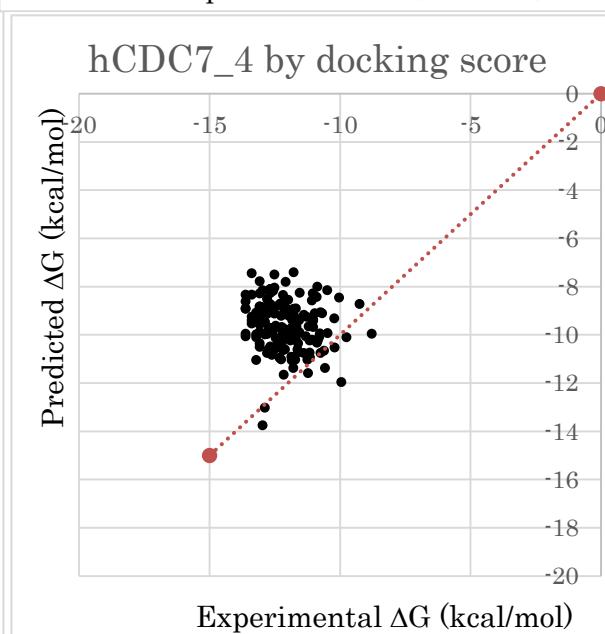

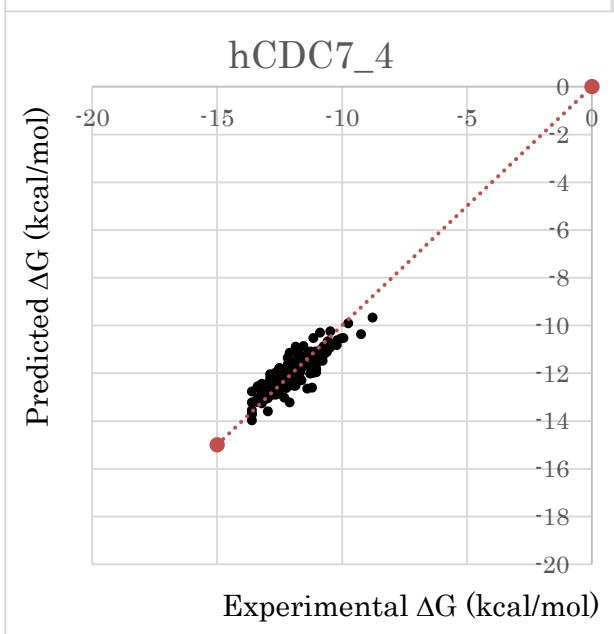

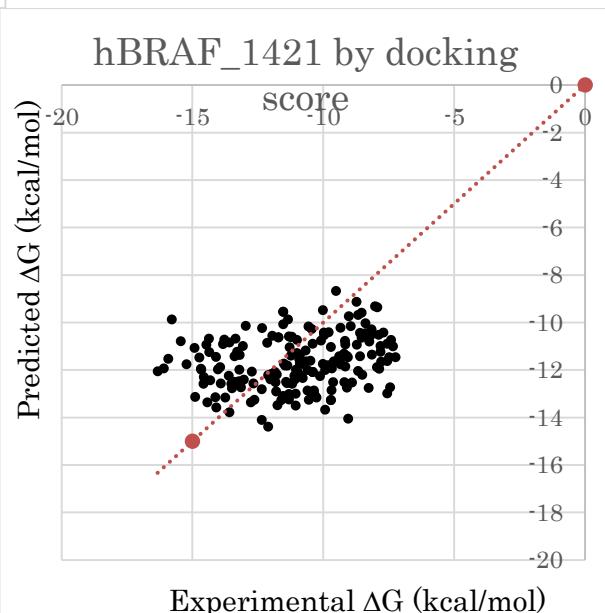

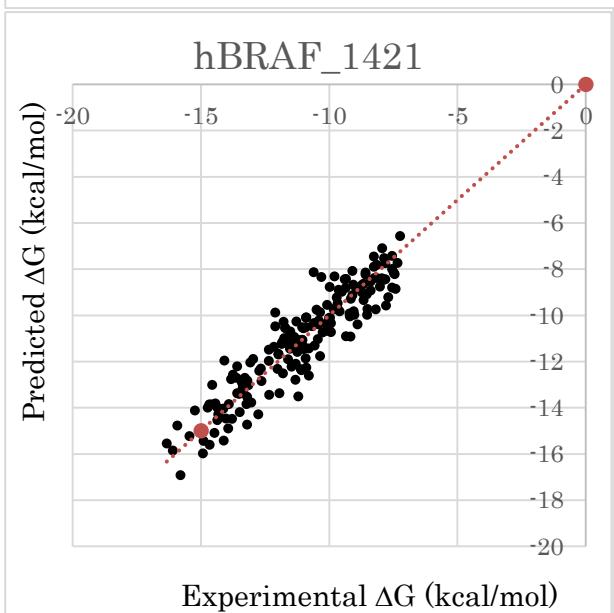

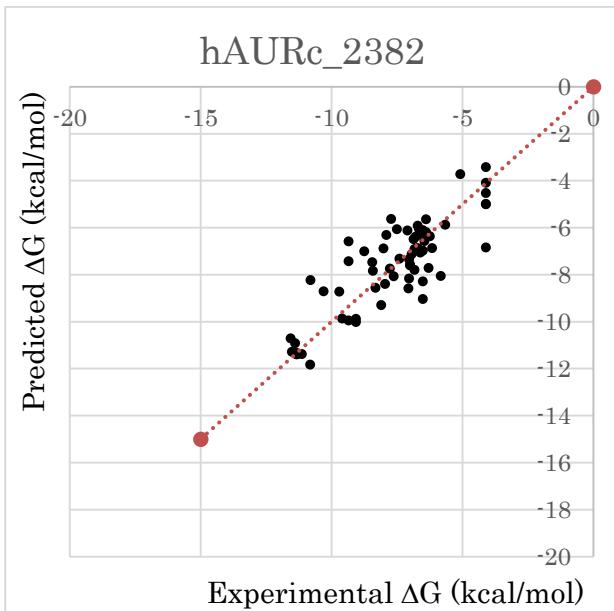

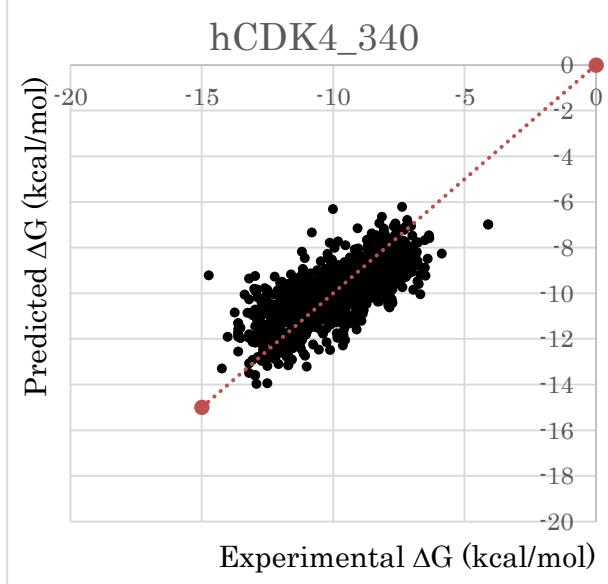

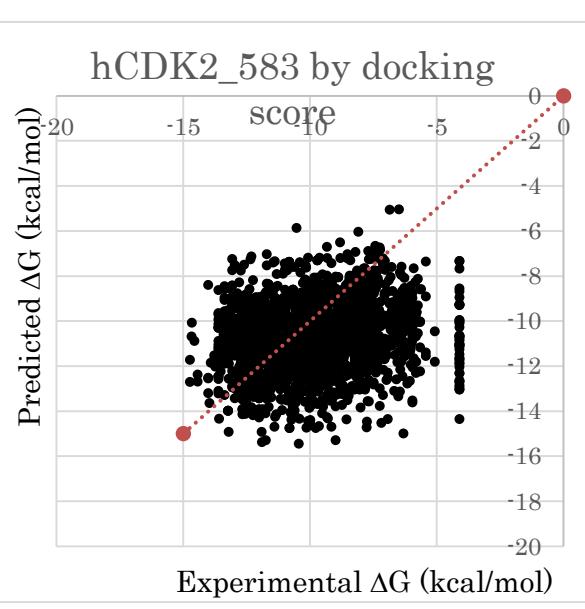

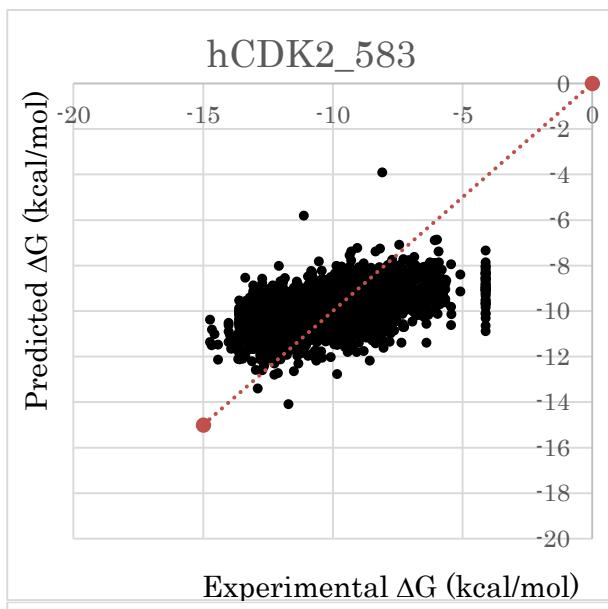

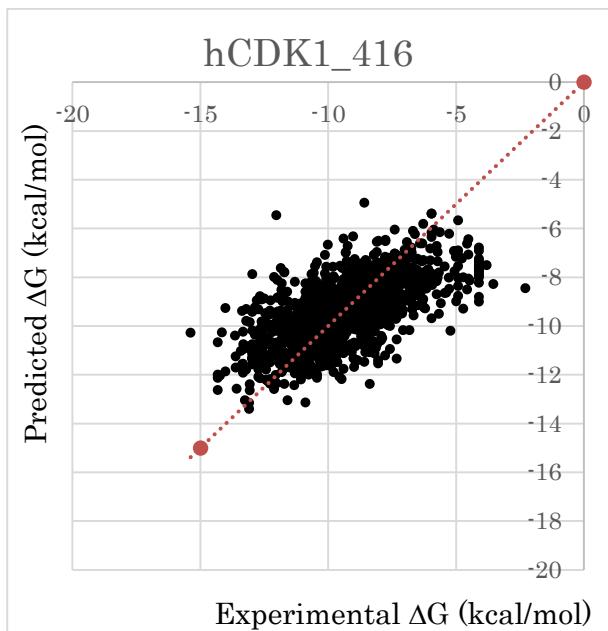

**Figure S2** Correlation between the calculated and experimental  $\Delta G$  values. The 4-fold cross validation results by the docking score QSAR method ( $\lambda=0.005$ ,  $W=20$ ,  $N=0.8$ ) are in the left column. The naive docking results are in the right column (shown as „\_by\_docking“). The orange dotted lines are the  $y=x$  lines.

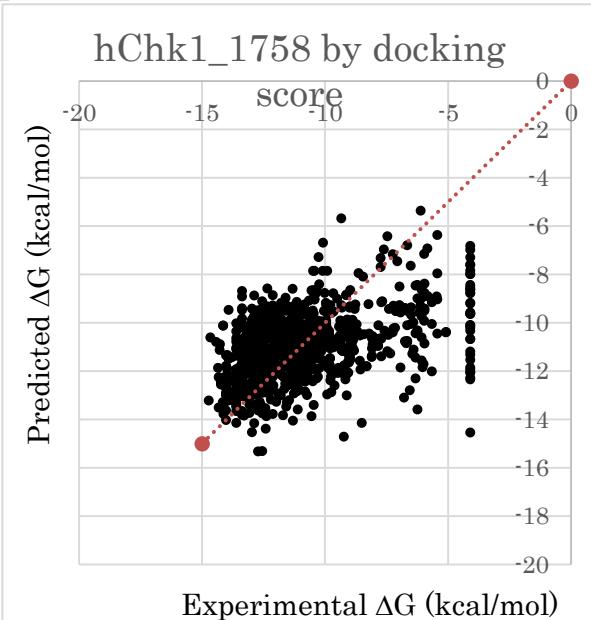

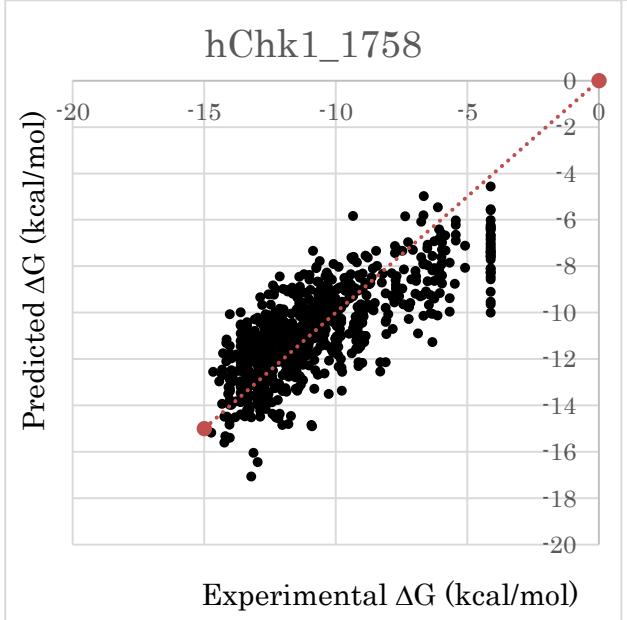

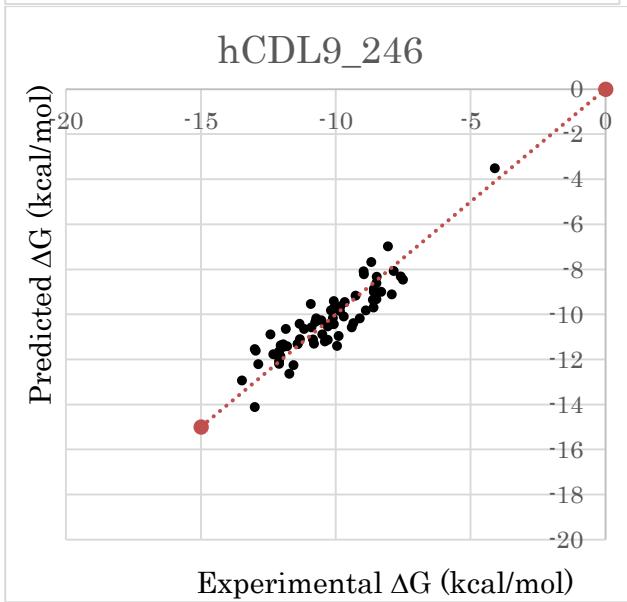

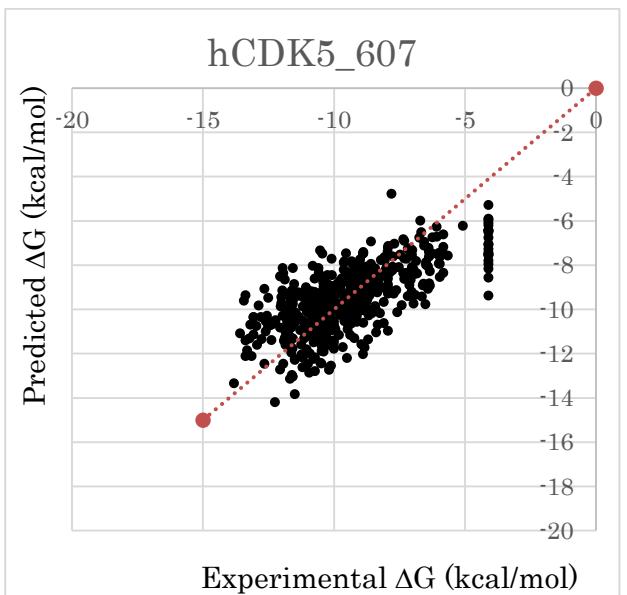

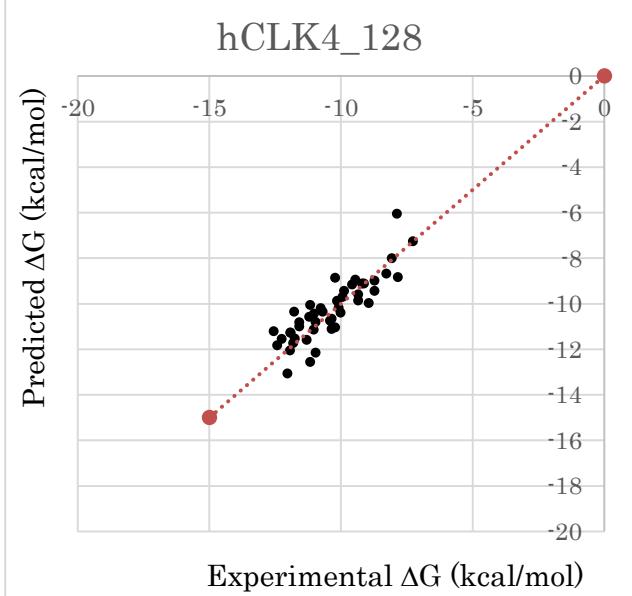

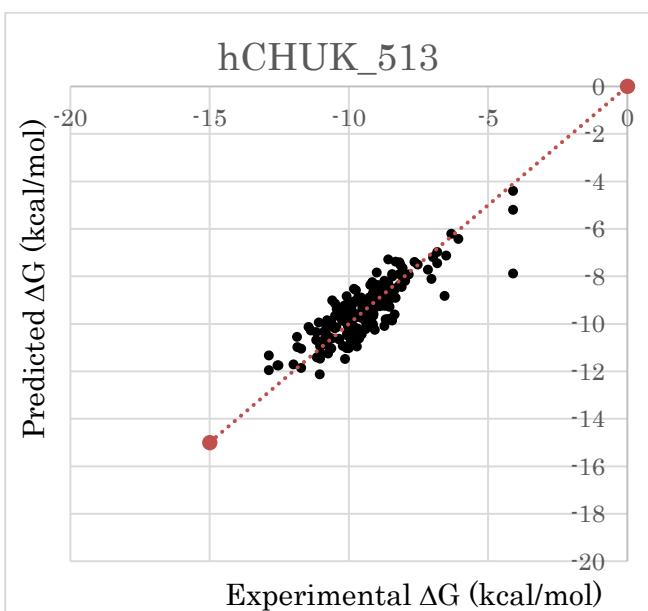

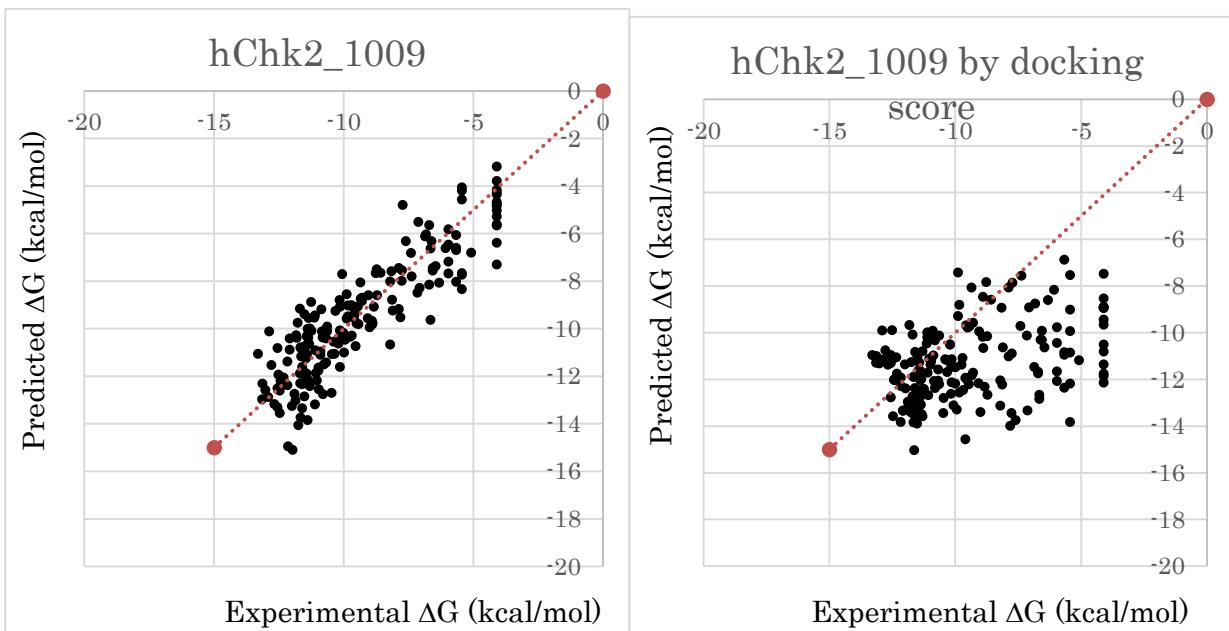

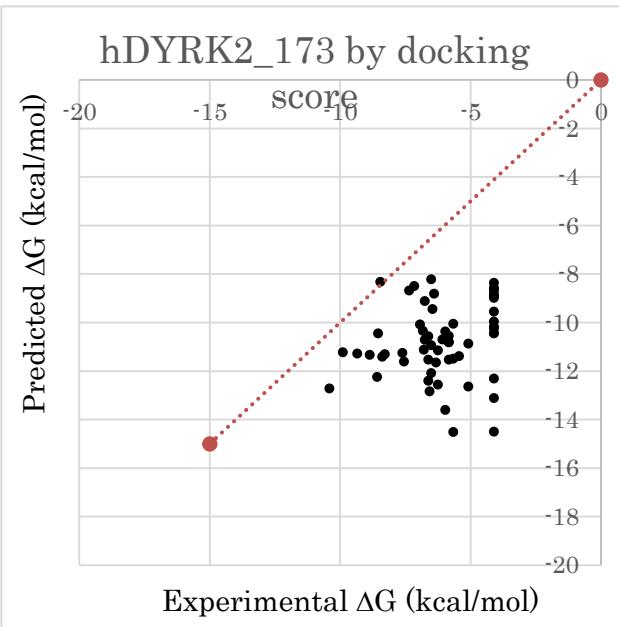

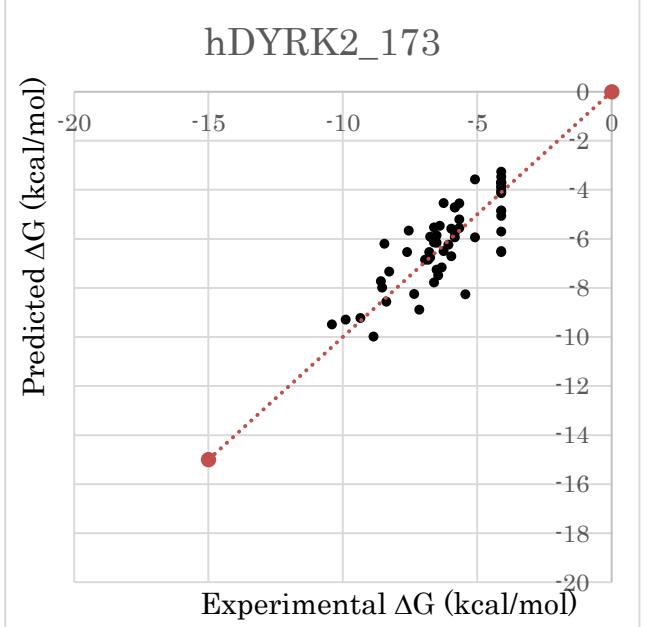

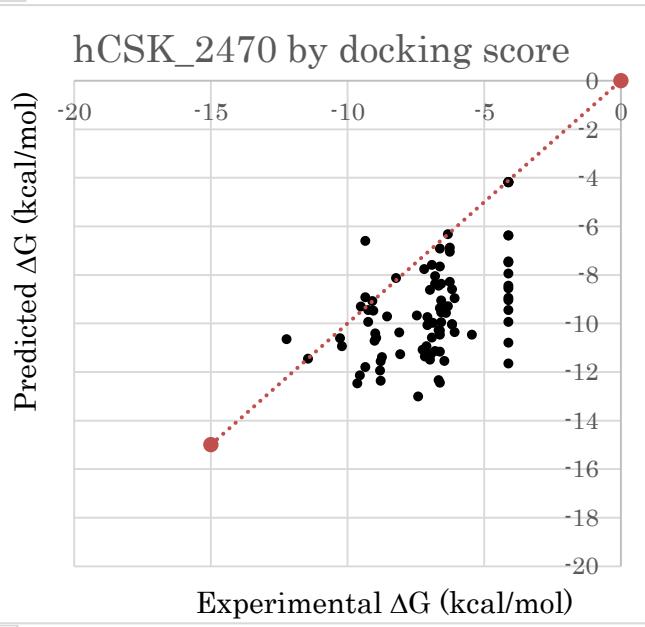

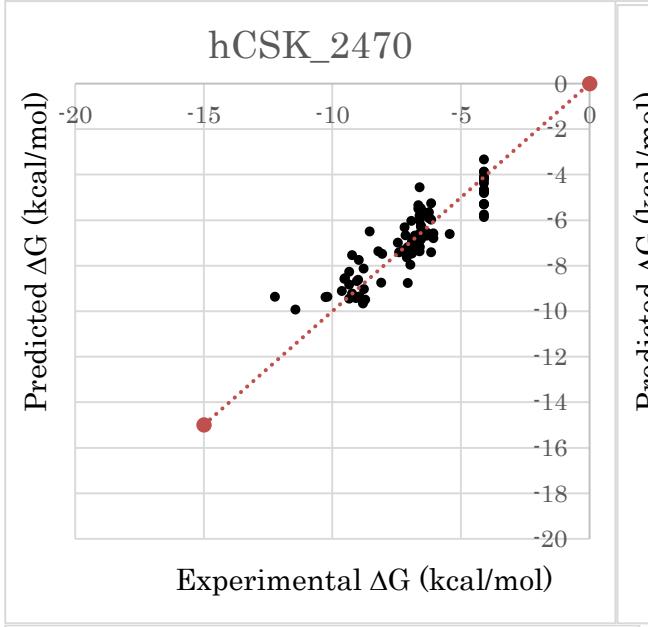

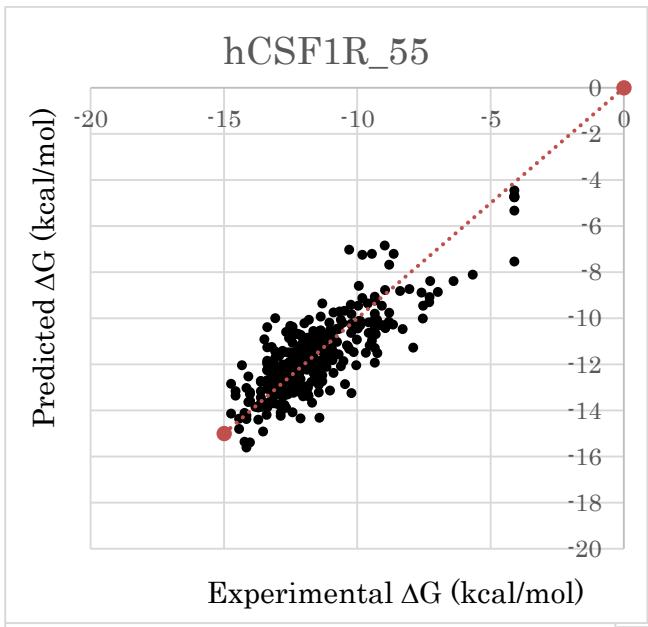

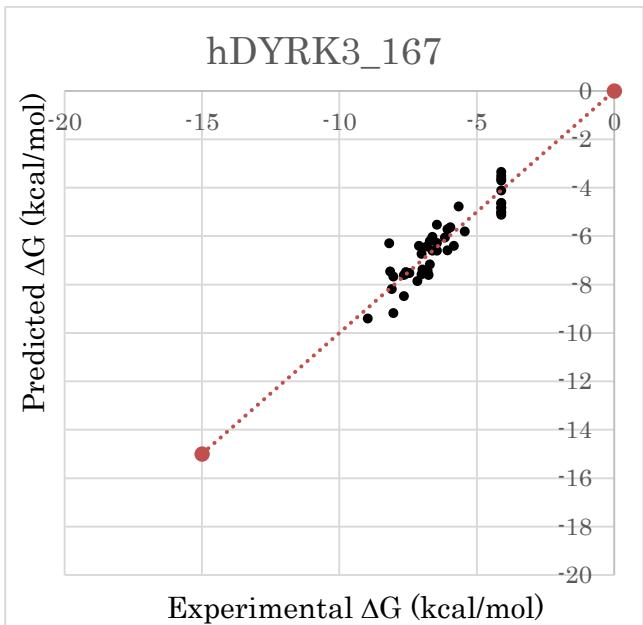

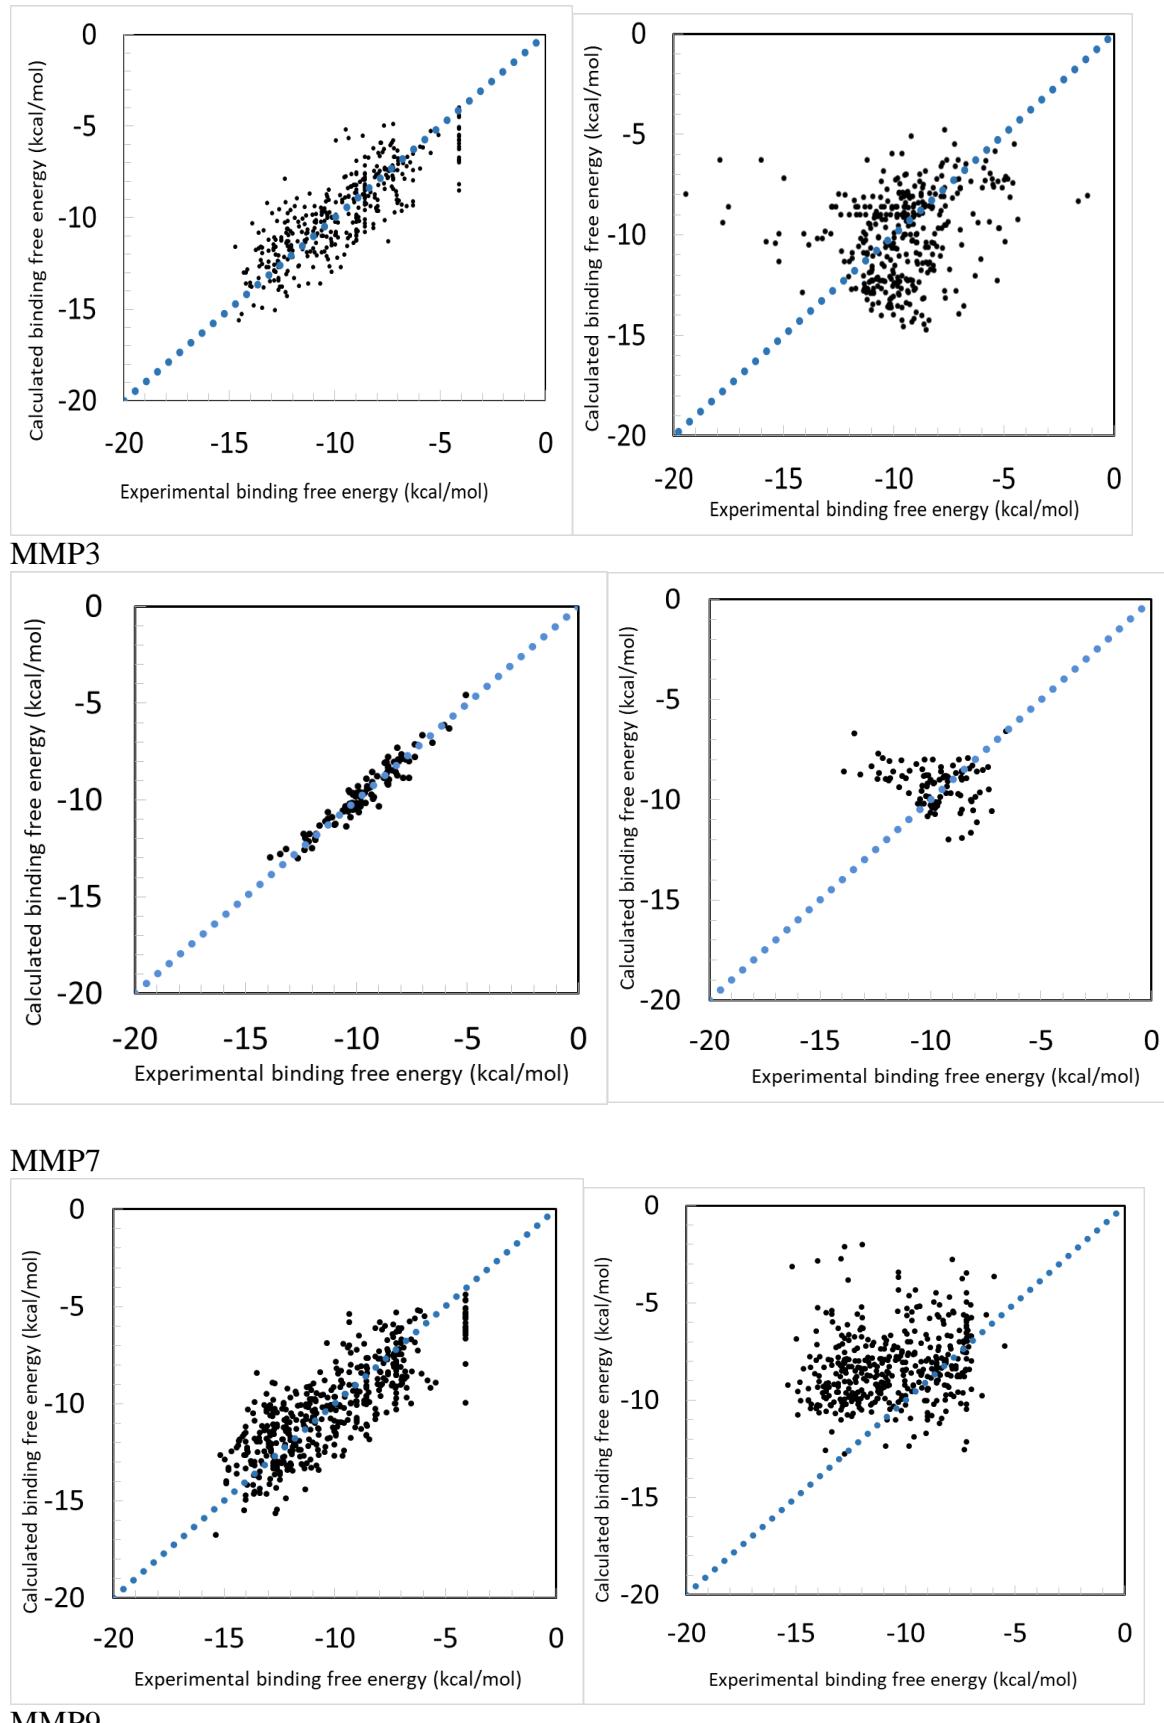

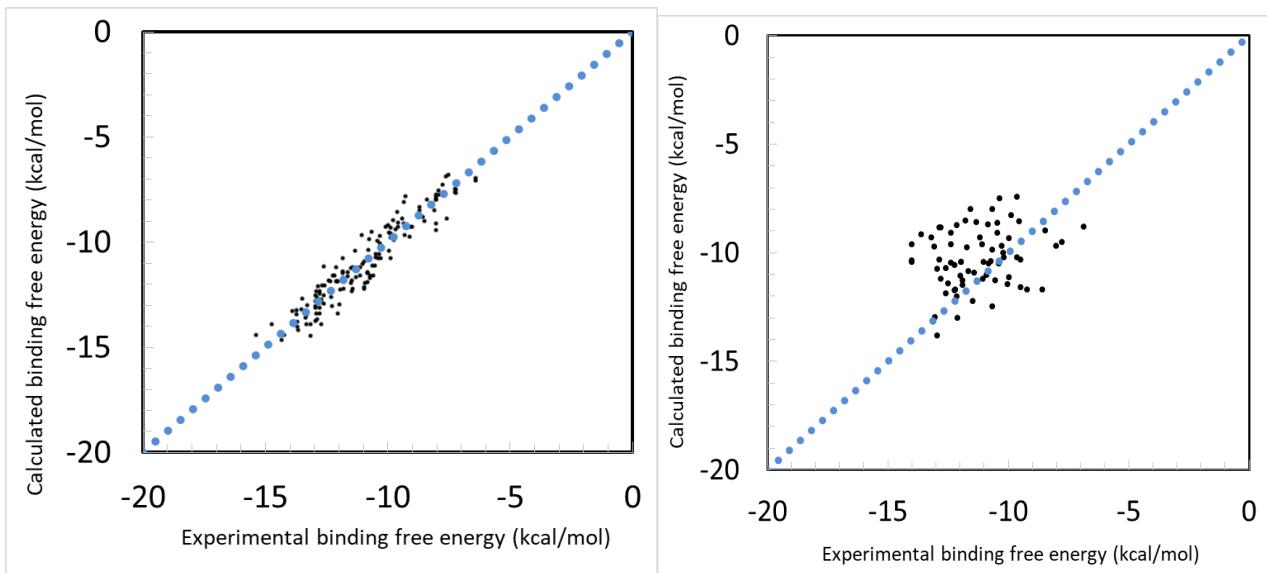

**Figure S3** Correlation between the calculated and experimental  $\Delta G$  values. The LOO cross validation results by the docking score QSAR method ( $\lambda=0.002$ ,  $W=20$ ,  $N=0.5$ ) are in the left column. The naive docking results are in the right column. The blue dotted lines are the  $y=x$  lines.
