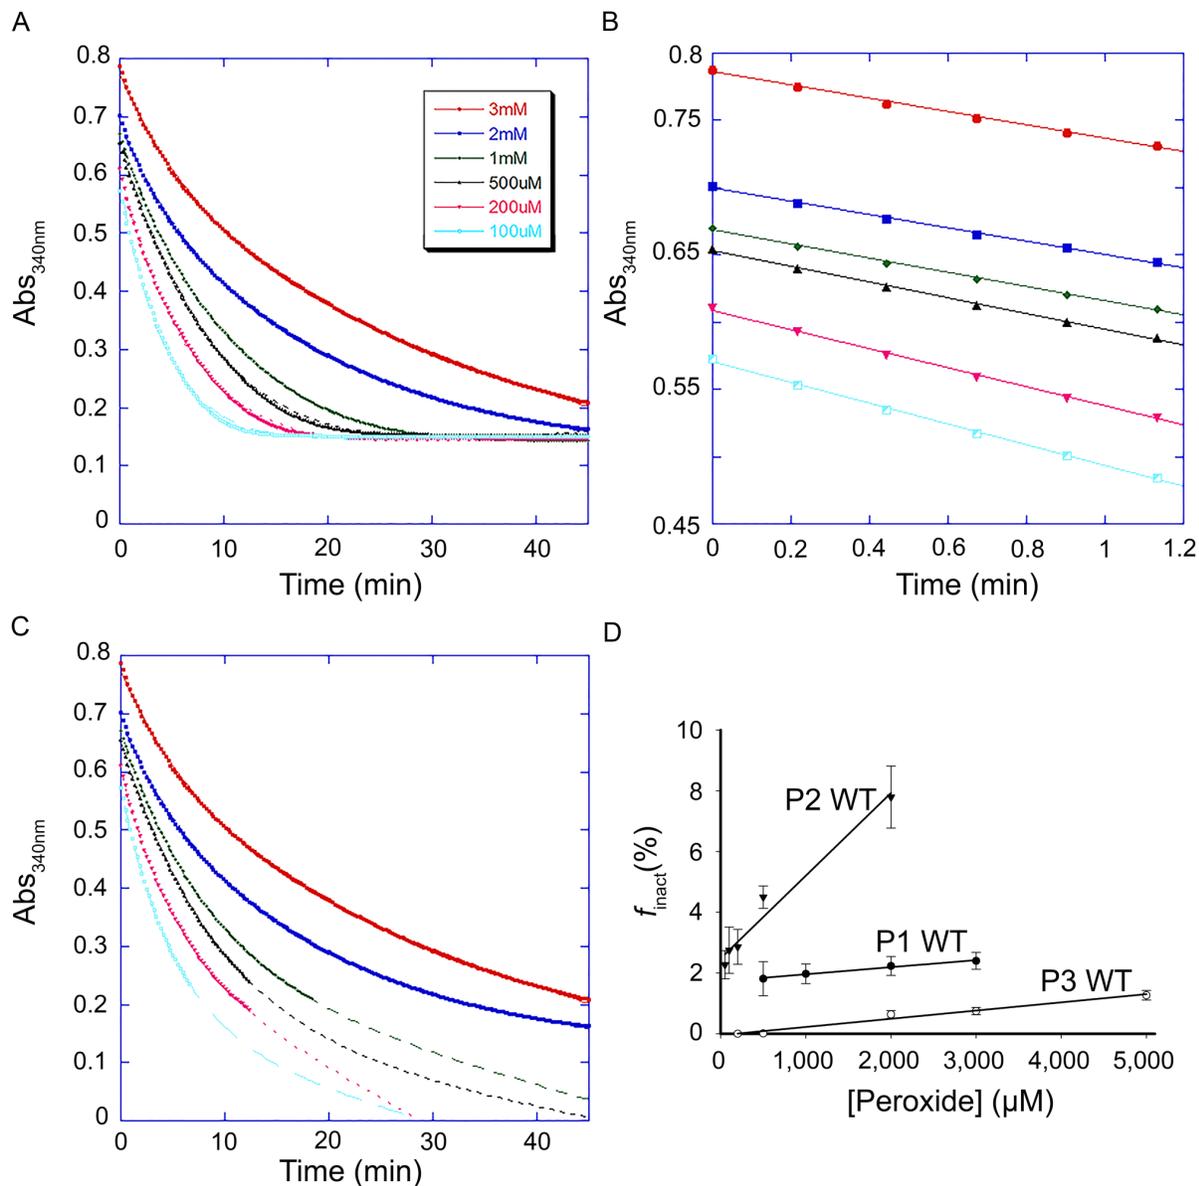

Figure 1. Kinetic analysis of hPrx1-3 reveals 3-25-fold differences in hyperoxidation sensitivity. *A*, Representative plot of the loss of Prx1 peroxidase activity. Activity was determined by monitoring the decrease in absorbance over time at 340 nm, from the consumption of NADPH by the *E. coli* Trx-TrxR-NADPH system. The reaction mixture was optimized for each Prx variant tested in this study and contained the following components and final concentrations: 0.25-2.5 μM Prx, 5-10 μM Trx, 0.2-0.5 μM TrxR, 150 μM NADPH. H_2O_2 was added to a final concentration of 50-5000 μM to start the reaction. The reactions were performed at 25°C. The curvature in the plot at later time points illustrates the Prx inactivation process, especially with increasing peroxide concentration. All Prx proteins and peroxide concentrations used within this study were analyzed on 3 or more separate days with fresh aliquots of each protein (Prx, Trx and TrxR) and H_2O_2 . Each day included 3-4 technical duplicates. *B*, Slope of the initial linear portion used to approximate the $k_{\text{SS}}K_{\text{LU}}$ rate. The slope of the initial linear portion was determined using the readings from the first five time points. The peroxide concentrations used are indicated in the legend within panel *A*. Please see the methods section for a description of the rationale for this procedure and the equations used. *C*,

Exponential decay rate used to approximate the rate of inactivation, $k_{\text{SO}_2\text{H}}$. The raw data was fit to equation 4. *D*, Plot of fraction inactivated, f_{inact} , versus peroxide concentration. The exponential rate was divided by the initial linear rate to give the f_{inact} at each peroxide concentration. The reciprocal of the slope of this plot divided by 100 is the $C_{\text{hyp}1\%}$ value. All data were used for f_{inact} and $C_{\text{hyp}1\%}$ calculations. The $C_{\text{hyp}1\%}$ values determined for hPrx1, hPrx2, and hPrx3 were as follows: 50 μM , 5 μM , and 127 μM , respectively.

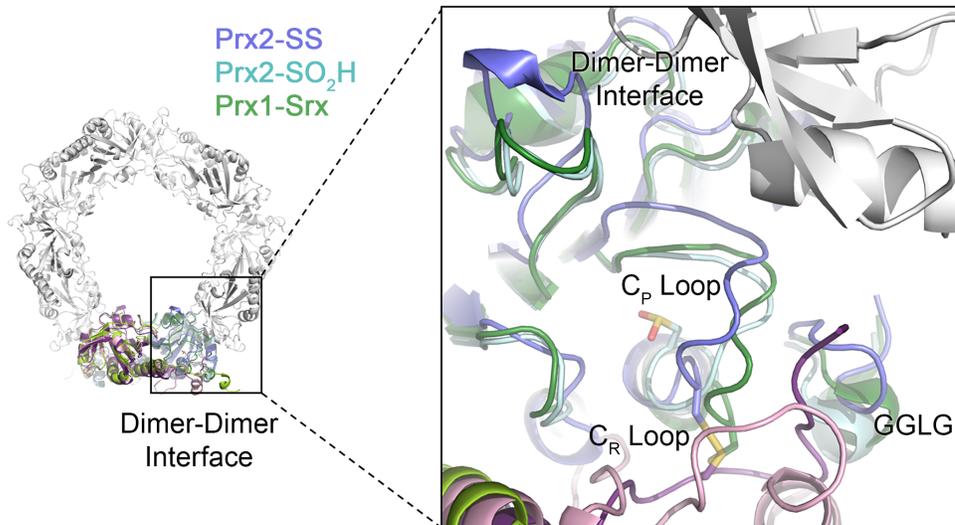

Figure 2. Superposition of human Prx2 and human Prx1 structures. Prx2-S_PS_R and Prx2-S_PO₂H are colored the same as in Fig. 2. The Prx1 (locally unfolded) molecule from the Prx1-Srx complex is shown in green; Srx has been omitted for clarity (PDB code 2RII) (22). The adjacent dimers of the toroid are shown in white. A close-up view shows numerous positional changes of the loops at the dimer interface, the GGLG motif, and the loops that contain the Cys-S_P and Cys-S_R residues (C_P loop and C_R loop). The hyperoxidized Cys51 of Prx2 is in the center of the view for reference.

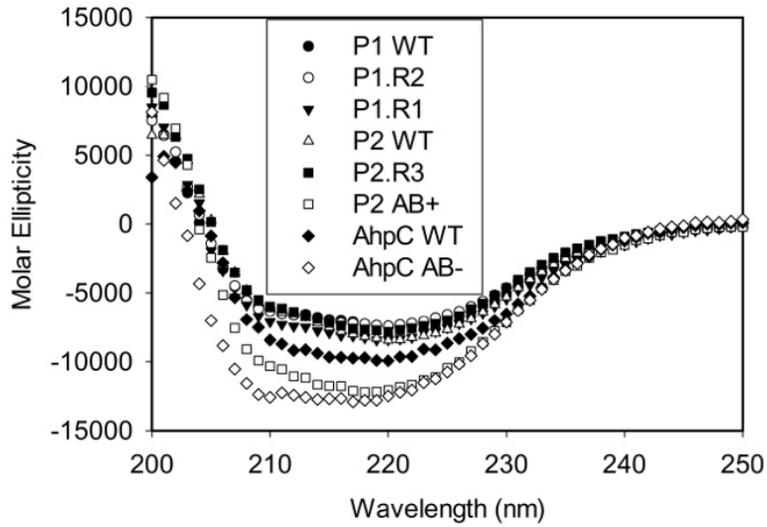

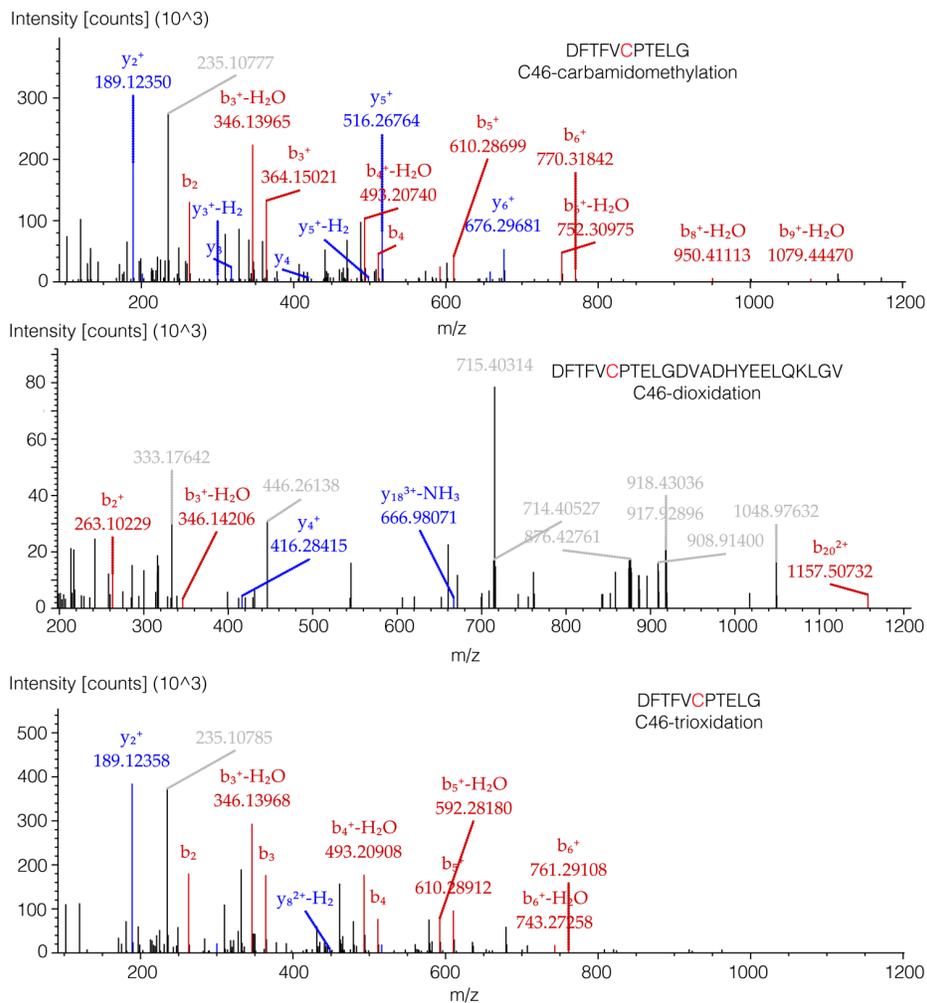

Figure 4. Assessment of all protein constructs by circular dichroism. Samples were pre-reduced with 10mM DTT for a minimum of 30 minutes and then desalted. Afterwards, proteins were diluted to approximately 20 μ M in 7 mM phosphate buffer saline (PBS). CD spectra were scanned over wavelengths from 250-180 nm with three technical repeats and averaged. Molar ellipticities and helical content were calculated from the averaged data. CD spectra were repeated 2-3 times on separate days with three technical repeats each day. See supplemental Table 3 for melting temperatures and helical content analysis.

	-H ₂ O ₂	+H ₂ O ₂	-H ₂ O ₂	+H ₂ O ₂	-H ₂ O ₂	+H ₂ O ₂
Ratio of Oxidized Species Relative to Untreated Controls	1.0	1.2	1.0	1.0	1.0	11.0

Figure 5. MS/MS spectra of AhpC C46-containing peptide in representative oxidized states. (top) carbamidomethylated peptide resulting from blocking of reduced thiol with iodoacetamide, (middle) oxidized -SO₂H state, and (bottom) oxidized -SO₃H state. The Table represents a summary of the ratios of -SO₂H and -SO₃H states in H₂O₂ treated samples relative to the untreated controls. The ratios were calculated using the peak area of the respective extracted ion chromatogram in each sample using Skyline. The bar graph representation of the data is shown in Fig. 4F of the main text.
