Supplementary Table 1

Table S1. Phase-locking strengths do not correlate with burstiness or firing rate. For each frequency band, a correlation (Pearson's) is taken between the phase-locking resultant vectors and burstiness (top row) or firing rates (bottom row) for all neurons (N=780). R and P values are shown for each frequency band.

Table S2. Phase-locking resultants do not correlate with task phase–specific firing or power/rate correlations. (**A**) Three groups of neurons when clustering (K-means) was performed on power/rate correlations (Fig. 3F right column). No group of neurons had a distribution of phase-locking resultant vectors that was significantly different from a randomly selected equal number of neurons (**B**) Three groups of neurons when clustering (K-means) was performed on task-phase specific firing patterns (Fig. 3F left column). No group of neurons had a distribution of phase-locking resultant vectors that was significantly different from a randomly selected equal number of neurons.

A

Categorized by rate/power correlation

B

Categorized by mean rate over task phases
