Computational details

Light-absorption features. The light absorption of motors **1a–4d** was investigated in the following way, using Dunning's correlation-consistent polarized valence triple- ζ (cc-pVTZ) basis set^[1] for all steps and considering each of the E_{out} , Z_{in} , E_{in} and Z_{out} isomers (although being enantiomers, the results for E_{out} and E_{in} are identical, as are the results for Z_{out} and Z_{in}). First, the ground-state (S_0) equilibrium geometries of the motors were optimized with the complete active space self-consistent field (CASSCF) method.^[2] Based on the resulting geometries, the same method was then used to calculate the wave function at the vertical Franck-Condon (FC) point in the bright and photoactive first excited singlet $\pi\pi^*$ state (S_1) of each species. Finally, from these wave functions, single-point calculations were performed with complete active space second-order perturbation theory (CASPT2)^[3] to obtain vertical $S_0 \rightarrow S_1$ excitation energies. The corresponding oscillator strengths were obtained with the complete active space state-interaction (CASSI) method.^[4] All CASSCF and CASPT2 calculations were carried out with active spaces comprising the full π -systems of the motors, i.e., utilizing CAS(6,6), CAS(8,8) and CAS(10,10) for **1a–1d**, **2a–2d/3a–3d** and **4a–4d**, respectively. As a complement to the CASPT2//CASSCF results, vertical excitation energies (both $S_0 \rightarrow S_1$ and $S_0 \rightarrow S_2$) were also calculated using the approximate coupled-cluster singles and doubles (CC2) method^[5] within the resolution-of-the-identity (RI) approximation.^[6,7] These calculations were based on S_0 equilibrium geometries optimized with Møller-Plesset second-order perturbation theory (MP2).

Enantiomerization barriers. The $E_{\text{out}} \leftrightarrow E_{\text{in}}$ and $Z_{\text{out}} \leftrightarrow Z_{\text{in}}$ enantiomerization free-energy barriers of motors **1a–4d** were calculated in the gas phase and in non-polar (cyclohexane) and polar (water) solvents using both MP2 and density functional theory (DFT) methods in

combination with the cc-pVTZ basis set. The solvents were described with the SMD continuum solvation model^[8] and the DFT calculations were carried out with the B3LYP and M06-2X^[9] global and the ω B97X-D^[10] range-separated hybrid functionals. Following S_0 equilibrium geometry optimization of the four motor isomers and the enantiomerization transition structures that connect them, frequency calculations were performed to obtain Gibbs free energies (at room temperature) of the resulting geometries and to ensure that these do correspond to minima (real vibrational frequencies only) or transition structures (one imaginary vibrational frequency). Throughout, the MP2/B3LYP/M06-2X/ ω B97X-D geometries were subjected to MP2/B3LYP/M06-2X/ ω B97X-D frequency calculations, respectively. Thereby, the enantiomerization free-energy barriers predicted by any of the methods stem exclusively from calculations with that very method.

MEP calculations. The photoisomerization minimum energy path (MEP) calculations on motors **1d/2d/3d/4d** were started from the S_1 FC points at the CASSCF S_0 equilibrium geometries of the E_{out} , Z_{in} , E_{in} and Z_{out} isomers, and were performed using state-averaged CASSCF (SA-CASSCF) in combination with Dunning's correlation-consistent polarized valence double- ζ (cc-pVDZ) basis set.^[1] Employing equal (0.5) weights for S_0 and S_1 in the state-averaging, the MEP calculations were done with the same active spaces as the light-absorption calculations (i.e., with CAS(6,6), CAS(8,8) and CAS(10,10) for **1d**, **2d/3d** and **4d**, respectively). For **4d** (MEPs in Figure 3), the S_0 and S_1 energies of the S_1 MEP geometries were refined through CASPT2 single-point calculations with the cc-pVDZ basis set, so as to account for dynamic electron correlation effects. For **1d/2d/3d** (MEPs in Figures S3–S5), on the other hand, no such refinement was deemed necessary, based on

a comparison in Figure S6 of the MEPs of **4d** obtained with and without CASPT2 single-point calculations. Indeed, as can be seen from Figure S6, the two sets of MEPs are very similarly shaped.

NAMD simulations. The non-adiabatic molecular dynamics (NAMD) simulations of the photoisomerizations of motor **4d** were carried out using SA-CASSCF(10,10), with equal weights for S_0 and S_1 , in combination with Ahlrich's split valence plus polarization double- ζ (SVP) basis set.^[11] First, for each of the E_{out} , Z_{in} , E_{in} and Z_{out} isomers, 10 different initial nuclear configurations and velocities were generated from a harmonic-oscillator Wigner distribution^[12,13] of the corresponding S_0 vibrational normal modes calculated at the MP2/SVP level of theory. For each isomer, these initial conditions were then used to start 10 photoisomerization trajectories from the S_1 FC points. Evaluating nuclear forces “on the fly”, the trajectories were propagated classically for a maximum of 700 fs employing the velocity Verlet algorithm^[14] with a fixed integration time step of 1 fs.

During the simulations, the non-adiabatic coupling $\langle \Psi_1 | \frac{\partial}{\partial R} \Psi_0 \rangle$ between the S_1 and S_0 states was evaluated in the framework of Landau-Zener theory,^[15,16] using the algorithm by Robb and co-workers^[17,18] as implemented in the MOLCAS 8.0 suite of programs.^[19] In this framework/algorithm, the coupling is large when $\langle \Psi_1 | \frac{\partial}{\partial t} \Psi_0 \rangle$ is large, as calculated using the numerical approximation

$$\langle \Psi_1(t) | \frac{\partial}{\partial t} \Psi_0(t) \rangle \approx \frac{\langle \Psi_1(t) | \Psi_0(t + \Delta t) \rangle}{\Delta t}.$$

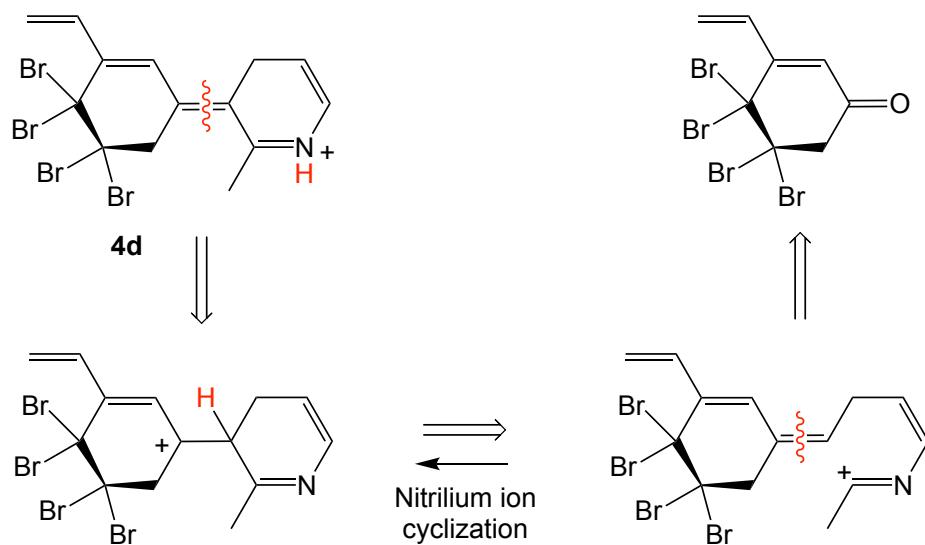

Performing this calculation at each step along the trajectories for which the energy gap between the two states is smaller than 0.03 a.u., a trajectory was allowed to hop from the S_1 state to the S_0 state subject to the condition that $\langle \Psi_1(t) | \Psi_0(t + \Delta t) \rangle$ exceeds a default value (0.25) signaling the

proximity of a S₁/S₀ conical intersection region (by virtue of the associated deviation of the S₁ and S₀ wave functions from orthogonality). Qualitatively, the procedure to only allow a single hop between the two states (from S₁ to S₀) has been validated in previous NAMD simulations of motor **1a**, which showed that increasing the number of allowed hops does not affect the predictions of key quantities like photoisomerization times and quantum yields by more than 10%.^[20]

Software used. The MP2 and DFT calculations were done with Gaussian 09.^[21] The CC2 calculations were done with TURBOMOLE 6.6.^[22,23] All other calculations were done with MOLCAS 8.0.^[19]

Retrosynthetic analysis and Scheme S1

As shown by Lumento et al.^[24] who built on earlier work by Gawley and Chemburkar,^[25] photoisomerizable Schiff-base systems can be synthesized through nitrilium ion cyclization onto an indanylidene moiety. Thus, using a nitrilium ion that upon cyclization yields a dihydropyridinium motif and replacing indanylidene with a tetrabrominated cyclohexenylidene, a retrosynthetic analysis for the preparation of motor **4d** can be summarized as in Scheme S1.

Scheme S1. Retrosynthetic analysis for the preparation of motor **4d**.
