Supplementary Figures:

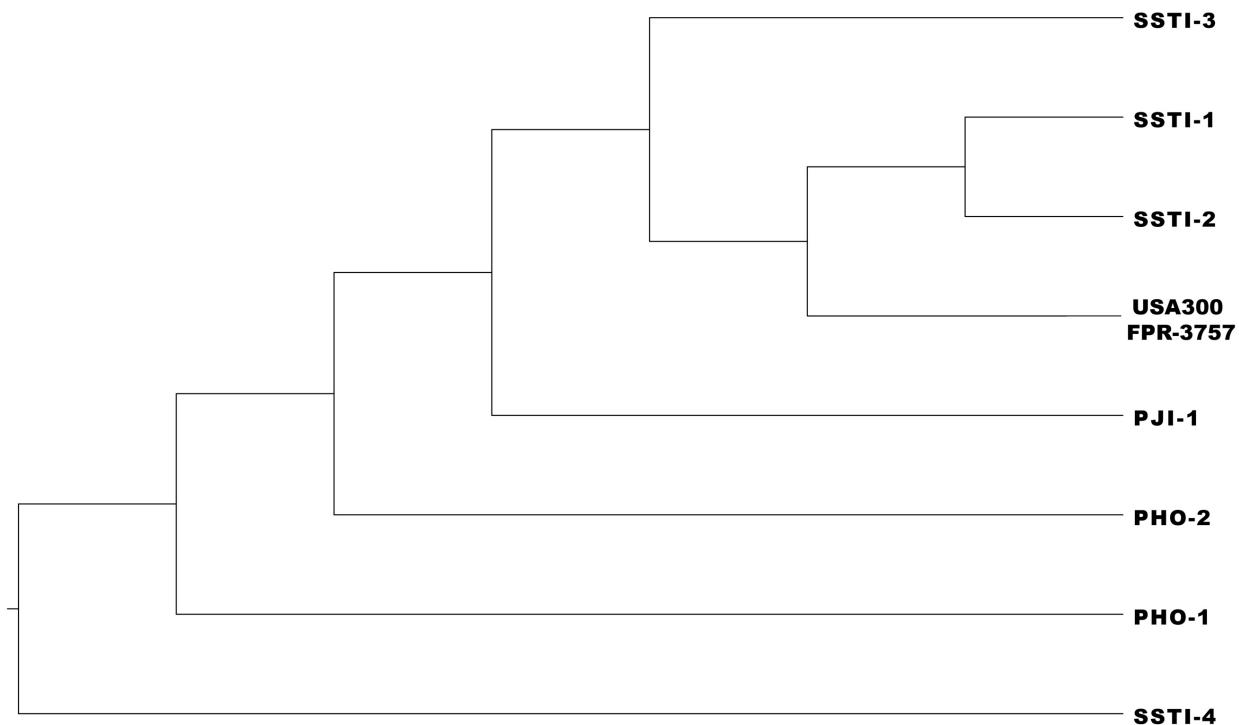

Supplementary Figure S1. IgG fold-change between acute and convalescent visits in *S. aureus* by bead-based multiplex assay. A custom bead-based multiplex assay was used to analyze serially-diluted patient serum samples (acute, short-term follow-up, long-term follow-up), and fold-changes in IgG titer were determined by custom software analysis.

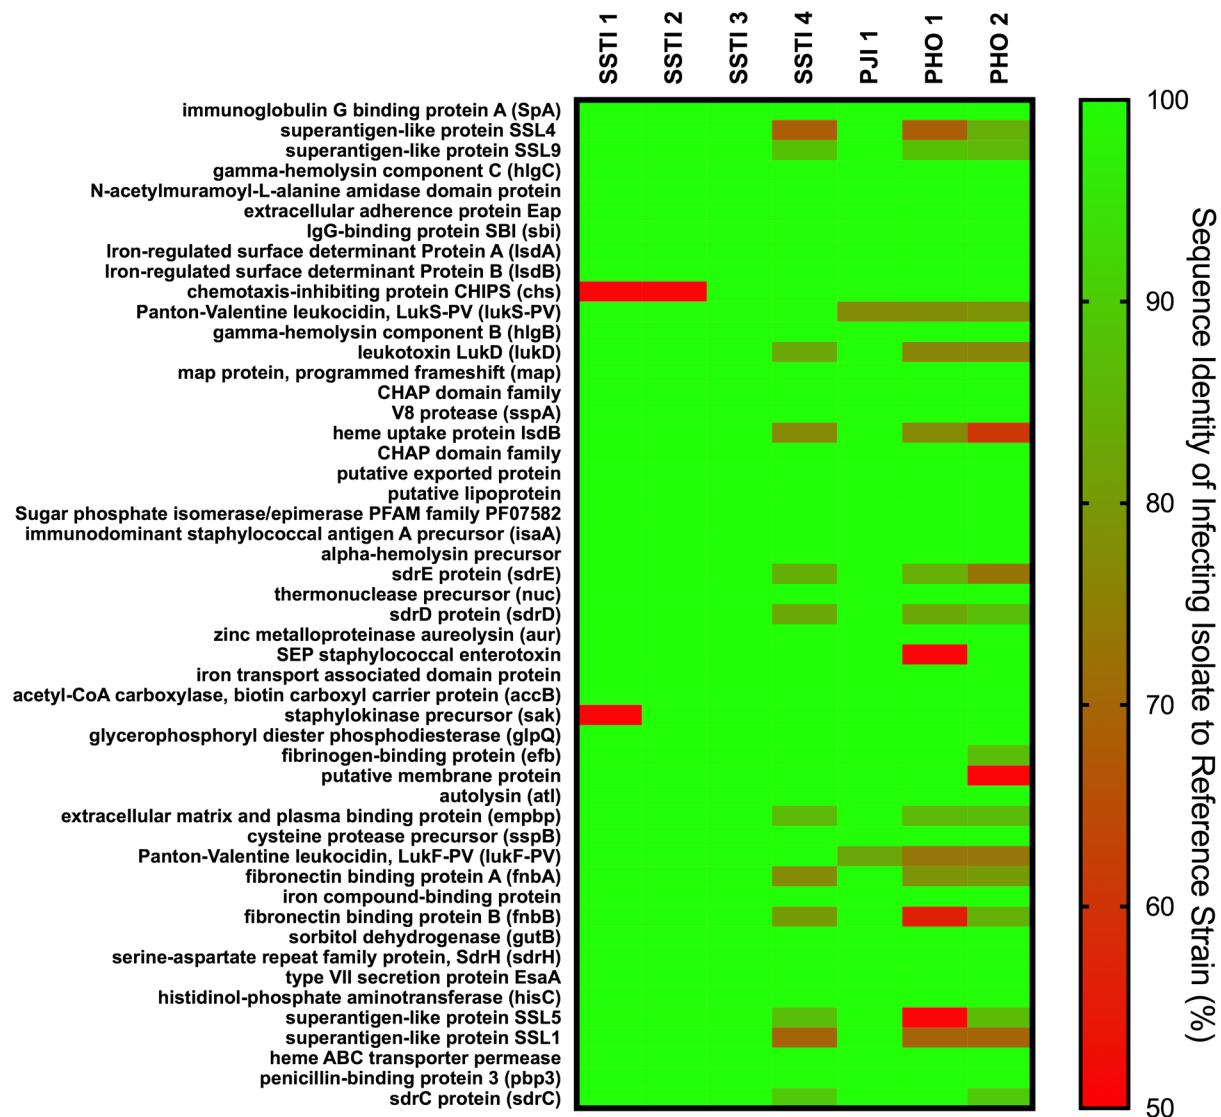

Supplementary Figure S2. Global serologic antibody responses of *S. aureus* infected patients against MRSA ORFs. Recombinant proteins from all ORFs (2652) from *S. aureus* strain USA300-FPR3757 were probed for binding of serum IgG from seven infected patients obtained at three different time points. Values were normalized for fluorescence intensity of control spots on each chip. Values above 1.0 were considered positively reactive as they are at least two-fold above background intensity for IgG-reactivity.

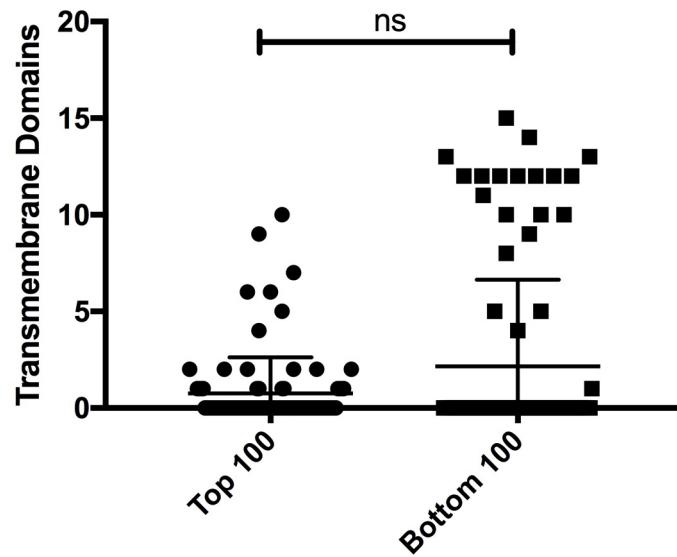

Supplementary Figure S3. Phylogenetic relationship between *S. aureus* infecting isolates and reference genome. The relationship between the seven patients infecting *S. aureus* isolates and the reference genome used in the protein array (USA300 FPR-3757). The assembled draft genome contigs were used as genome data for each isolate and the GenBank draft genome assembly for strain USA300 FPR-3757 (GCA_000013465) was used as a reference.

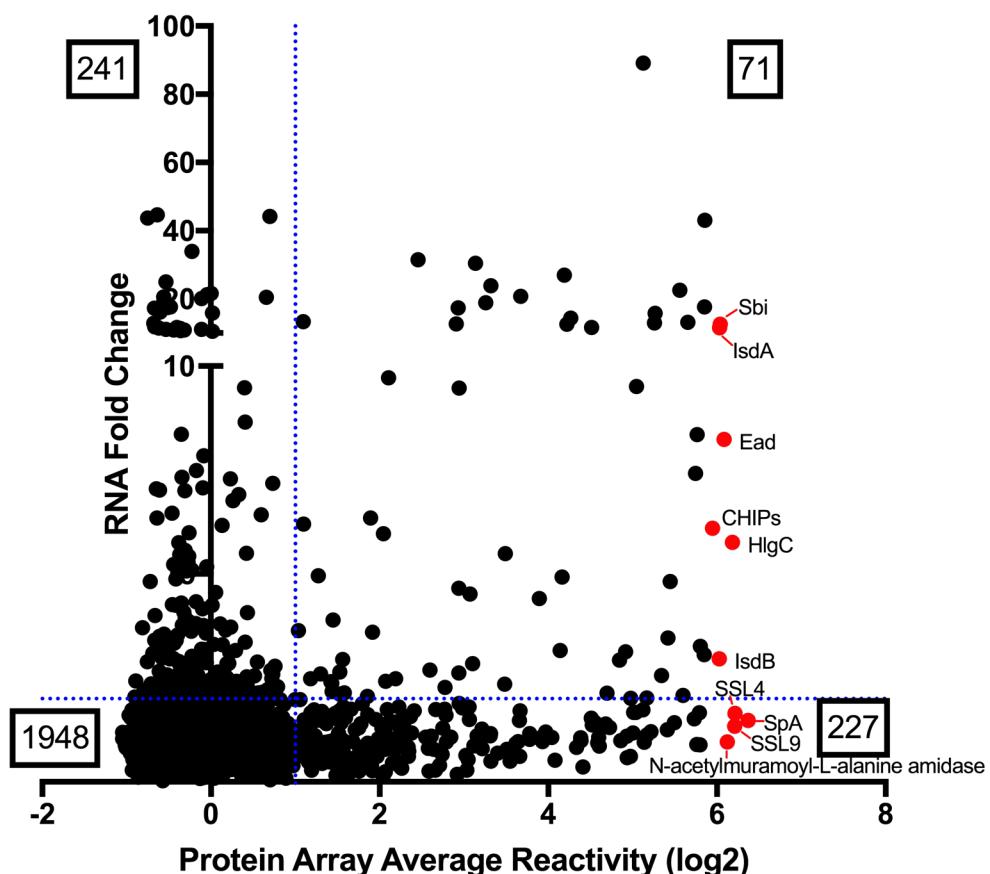

Supplementary Figure S4. Comparison of genomic content between reference and infecting *S. aureus* strains. Percentage amino acid identity deduced from genomic sequences was determined using a customized translated (tBLASTn) script for the ORFs for the top 50 IgG-reactive antigens from the protein array studies, with comparisons of the reference strain used in the array (USA300 FPR3757) with the sequence determined for the infecting strain for each patient. Amino acid sequence homology of 90% and above was generally considered a match for the representation of the gene of interest in infecting strain. Any percent identity below 90% could potentially be either a highly variant form of that protein or could be a match to a different protein with a related sequence. Proteins with percent identity below 50% are considered to be not present in that isolate.

Supplementary Figure S5: Transmembrane domain-containing proteins in top and bottom 100 proteins. ORF sequences from the top and bottom 100 proteins identified by immunoarray were analyzed with the TMHMM Server and the representation of transmembrane domains thereby predicted. There was no significant difference in transmembrane containing proteins between the top and bottom 100.

Supplementary Figure S6. IgG reactivity for *S. aureus* antigens by protein array correlates with the level of increased gene expression at the site of disease. We performed a Spearman correlation in GraphPad PRISM between IgG reactivity determined by protein array for each antigen with fold-change in RNA expression for each ORF from abscess infection, as reported by Date et al.³². The vertical dotted line is the cut-off for antigens of two-fold above background for IgG reactivity. Similarly, the horizontal dotted line represents the cutoff for gene expression of two-fold above background expression after in vitro culture. The number of antigens in each group are shown by the boxed number in each quadrant. The top 10 reactive proteins from the protein array are highlighted in red and labeled.

Supplementary Tables:

Supplementary Table S1. Antigens included in the multiplex bead-based assay. Ligands are assigned to categories; *S. aureus* antigens, or positive or negative controls. The full name and abbreviation of each antigen is indicated, as well as the source each antigen. The rank of IgG-reactivity for tested antigen in the chip-based protein array is also shown. N/A: Protein is not present in the array.

Supplementary Table S3. All antigens positive for IgG reactivity in at least one sample by protein array. Ranking was determined as in Table 3, and antigens are presented in this table if the reactivity was at least two-fold above background. Ranking number, locus tag and protein name/description is shown for each antigen.

Supplementary Table S4: Reactivity values of the 100 most IgG-reactive *S. aureus* antigen by protein immunoarray. IgG reactivity for each antigen was determined across all patients and samples, with ranking determined by overall mean reactivity, in addition to the presence of reactivity in each patient at each time point (see Methods).

Supplementary Table S5. Protein subsets based on differential IgG reactivity between infection groups. Proteins identified in each group of the Venn Diagram in Figure 1B. The cutoff for each group was an average reactivity for that infection group of 1 or above.

Supplementary Table S6: *S. aureus* patient isolates sequencing data. Patient infecting *S. aureus* isolates were collected at the time of presentation and sequenced as described in Methods. Key: -: negative; +: positive; ACME: arginine catabolic mobile element; CC: clonal complex; *pvl*: Panton-Valentine leukocidin; *SCCmec*: staphylococcal chromosome cassette *mec*.
^a Strains were assigned to clonal complexes using the MLST mapping feature at the Ridom SpaServer (<http://spa.ridom.de/mlst.shtml>), or a combination of typing methods¹.
