Figure 4

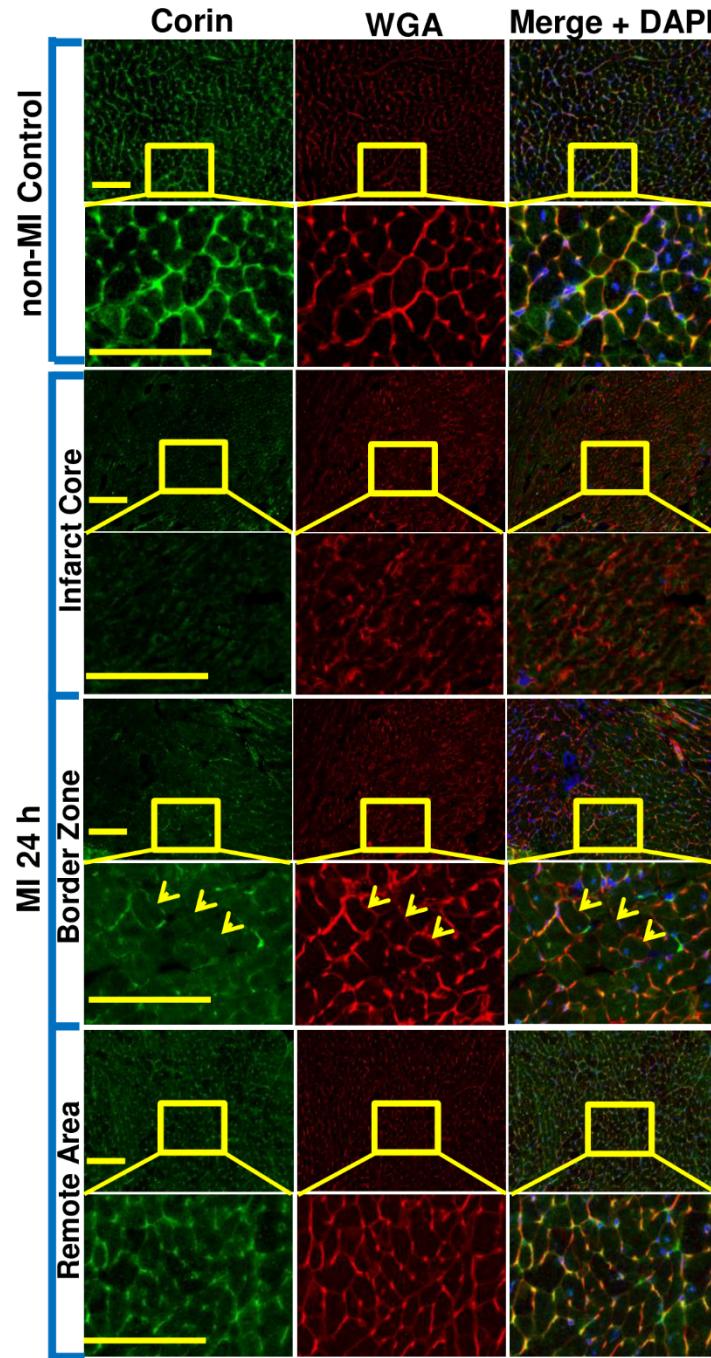

Fig 4.

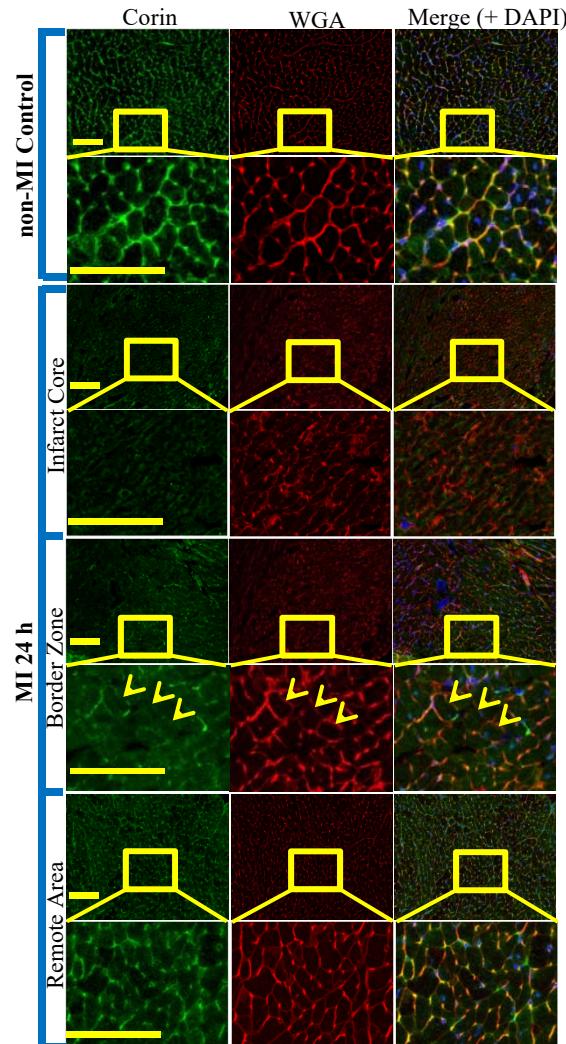

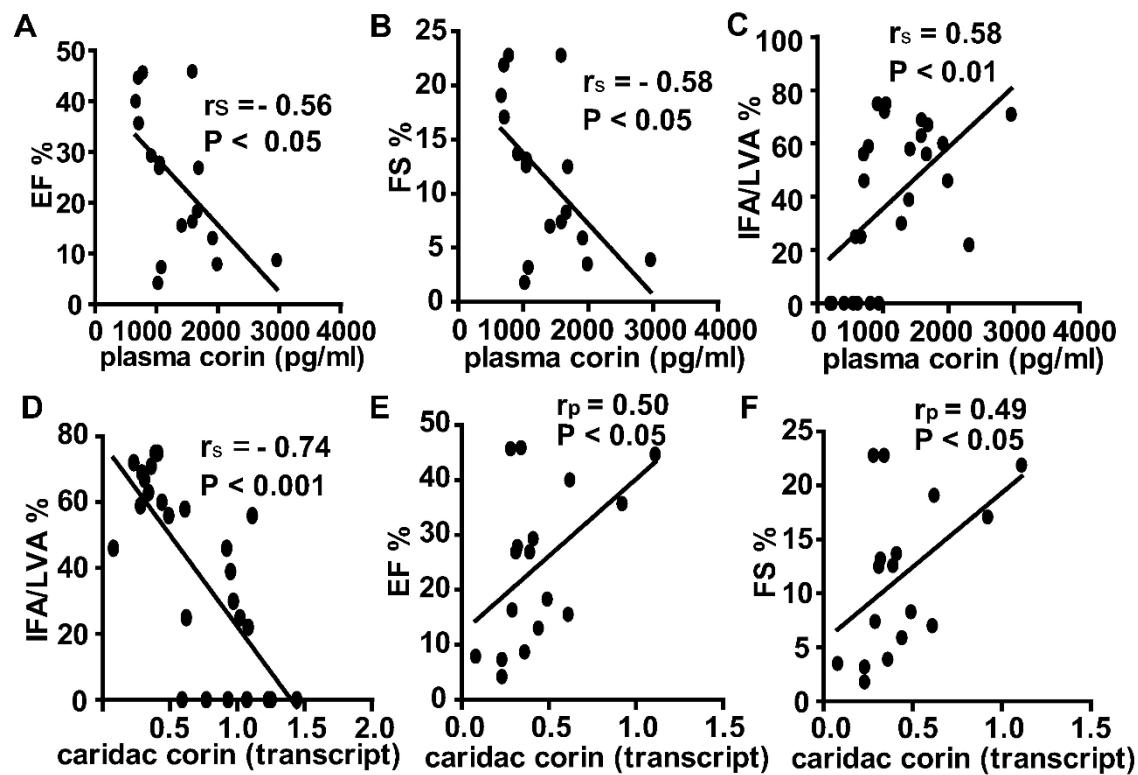

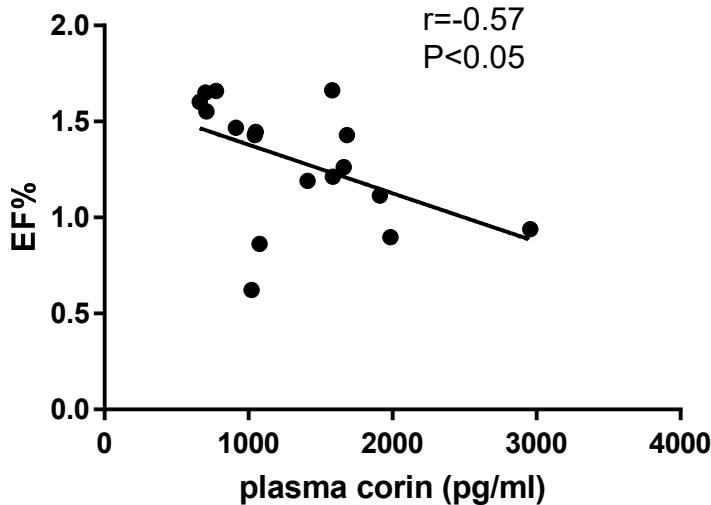

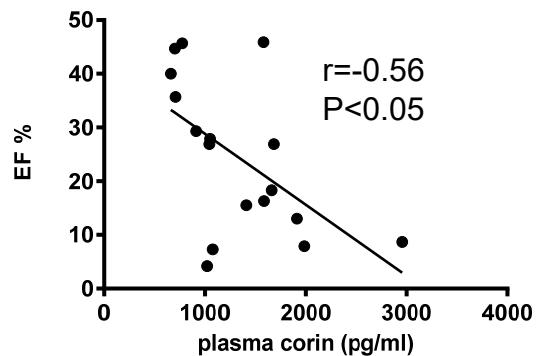

Fig 4. Spatial character of corin reduction in different regions of injured myocardium 24 hours post-MI.
Corin protein expression in non-MI and MI hearts assessed by double immunofluorescence (IF) staining on heart coronary sections with corin antibody followed by labelling with anti-rabbit AlexaFluor® 488 (green), WGA-Rhodamine (red) and counterstaining with DAPI (blue). Representative image of normal myocardium in left ventricle from non-MI hearts (row 1 & 2 panels) and infarct core region (row 3 & 4 panels) and border zone (row 5 & 6 panels) as well as remote area (row 7 & 8 panels) in MI hearts at low and high magnification (top vs bottom panels, bar=100 μ m). When compared to non-MI heart, corin expression in infarct core and border zone was significantly decreased while was relatively preserved in remote area. In addition, the integrity of cell membrane in infarct core was completely lost suggesting necrotic death. Border zone was transition area in which the cardiomyocytes with or without integrity of cell membrane were co-exist. Yellow arrows indicate three individual myocytes which show reduced corin expression (green channel) though the integrity of the cell membrane were well preserved (red channel). n = 4 mice per group.
