

1 **Supporting Information**

2 **Hydrogeology and Methane Occurrence**

3 Monitoring wells were installed in the two major Upper Devonian (UD) bedrock aquifers in the
4 study area: the Catskill Formation and the underlying Lock Haven Formation. These formations,
5 originally deposited in the late Devonian as part of the Catskill Alluvial Plain (1), have been
6 buried and uncovered since as a result of orogenic and glacial events. These are, therefore,
7 naturally fractured, dual-porosity aquifers close to the surface, and covered in some areas by
8 unconsolidated sedimentary or glacial alluvium (2, 3). Water yield from domestic drinking water
9 wells is higher in wells with fractures (3), indicating that fracture flow dominates flow patterns in
10 these aquifers. Water table variability in the region is inversely correlated to temperature, rather
11 than precipitation, and most recharge occurs after the spring thaw and in October, following first
12 frost and prior to the ground freezing (3). In the shallow subsurface, groundwater flow is
13 dominated by local flow systems (hilltop recharge zones and adjacent valley discharge zones),
14 and the regional flow system, that underlies smaller local flow systems, is governed by a
15 hydraulic gradient from south to north, and discharges in the Susquehanna River.

16 Stratigraphy in the UD is a series of interbedded sandstone, siltstone, and shale. Though some
17 shales are known to comprise the UD (4) and generate natural gas in non-commercial volumes
18 (5), the two economic gas production units that are thought to originate most of the stray
19 thermogenic methane in the region include: 1) Ordovician/Silurian hydrocarbon traps hosting
20 migrated hydrocarbons from Ordovician shales, and 2) Middle Devonian “tight gas” black
21 shales, including the Marcellus Shale (2, 6, 7). It is thought that thermogenic methane, known to
22 be present in the overlying UD aquifers and unrelated to SGD, genetically originated from one of
23 these two economic sources, and has migrated towards the surface over geologic time (2).
24 Conceptual models for migration include primary, secondary, and tertiary migration. Primary
25 migration would be movement of the hydrocarbons out of source rock, and, in some cases, into
26 an unconventional well. Secondary migration is the movement of hydrocarbons from the source
27 rock to a structural trap. Tertiary migration is the movement of hydrocarbons away from
28 structural traps, often induced by tectonic and climatic factors (2). Migration of gases through the
29 subsurface can lead to changes in chemical (decrease in longer chain hydrocarbon
30 concentrations) and isotopic composition owing to diffusive or solubility fractionation (8), and
31 observations of gas shows in the UD have demonstrated a gradually depleted, though still
32 thermogenic, signature (from -32.46 to -43.53 ‰) as distance to the surface decreases (5).

33 Sedimentary sequences of Upper Devonian bedrock dip approximately 1 to 3 degrees to the east
34 and south (9). In this region, and elsewhere, it has been shown that regional stress regimes
35 exhibit control on permeability in fractured rock terrains. In particular, normal faults and
36 topographic lineaments generally oriented in the NNE-SSW direction in this region have been
37 shown to be associated with the Cl-Br signatures of Appalachian Basin Brine (10). In addition,
38 valley stress relief has led to fractures that can enhance vertical transport of ABB within valleys
39 (3, 11). Within this region it is known that thermogenic methane can be naturally occurring, and
40 that the highest concentrations of thermogenic methane occur in valley settings where the water
41 well was completed in bedrock, and the bedrock well is confined on the surface by sedimentary

42 or glacial till (12). It is thought that the enhanced methane concentrations in these valley wells
43 are related to vertical stress-relief fracturing, the closer proximity to the methane-laced ABB, and
44 the confining sediment preventing methane from degassing to the atmosphere.

45 **Monitoring Well Installation**

46 Groundwater monitoring wells (MWs) were sited to investigate water quality and hydrologic
47 changes during a two year period in which seven shale gas wells were drilled, hydraulically
48 fractured, and entered production (Figure 1). The MWs were located on private properties, and
49 well placement was contingent on landowner permission, which placed some constraints on well
50 locations. Landowner agreements allowed for unregulated access to the monitoring wells, and
51 landowners were compensated in the amount of \$1000.

52 Vertical portions of gas wells targeting the Marcellus Shale in this study are drilled to depths of
53 ~2000 m, and the average depth of drinking water wells is between 35 and 90 m (2, 3, 9). To
54 drill the MWs, 10 cm steel casing was spun through unconsolidated material into the top of
55 bedrock, whereupon the bedrock was cored to depths of 90 to 120 meters below ground surface
56 with an HQ wireline coring system using potable water as the drilling fluid. Following drilling
57 and coring, borehole geophysics and straddle packer tests were used to determine location and
58 hydraulic conductivity, respectively, of fracture zones supplying water to the borehole. Borehole
59 geophysics included temperature, conductivity, optical televiewer, acoustic televiewer, acoustic
60 caliper, natural gamma ray, and heat-pulsed flow meter logging.

61 Solinst Waterloo 401 multi-level systems were installed in each borehole to isolate one to four
62 fracture zones. This system consists of stainless steel sampling ports, each with dedicated
63 pressure transducers and double-valve sampling pumps. The sampling ports draw water from 3-
64 m intervals (zones) that are isolated by permanent packers. Attempts were made to distribute the
65 ports over the entire depth of the bedrock portion of the borehole, while constraining placement
66 to fracture zones that would yield water. In total, 24 screened intervals were installed in eight
67 wells. Ports within each well were numbered from deepest to most shallow. For example, ports
68 in well A were numbered consecutively starting with the deepest port, A1. Details on depths of
69 wells and intervals are available in Table S1.

70 **Sampling Methodology and Sample Analyses**

71 Samples were collected via the low-flow purging and sampling method in which groundwater is
72 purged from sampling equipment, and then water is pumped at a rate <1L/min while monitoring
73 field parameters for stabilization (13). Low-flow purging and sampling has been shown to be
74 effective in wells with short screens and dedicated pumps (14), similar to the Waterloo 401
75 system. Following purging of the sampling equipment, groundwater was pumped at a rate
76 between 0.1 and 0.3 L/min while temperature, pH, DO, and specific conductance were monitored
77 at three minute intervals. When parameters stabilized across three time intervals, samples were
78 collected. Pressure data were collected continuously on an hourly basis from the time of well
79 installation. Samples were collected on a bi-weekly basis through July 2015, and continued, on
80 approximately a monthly basis, through May of 2017. From January 2015 to May 2017, 542
81 groundwater samples were collected, and each of the 24 intervals was sampled between 20 and
82 25 times. All samples collected were analyzed for methane and ethane concentrations, major
83 anions, major cations, trace metals, dissolved inorganic carbon (DIC), and dissolved organic

84 carbon (DOC). A subset of samples were analyzed for stable carbon isotopes of methane, $\delta^{13}\text{C-C}_2\text{H}_6$, $\delta^{13}\text{C -DIC}$, $^{87}\text{Sr}/^{86}\text{Sr}$, $\delta^2\text{H-H}_2\text{O}$, $\delta^{18}\text{O-H}_2\text{O}$, ^3H and CFC/SF₆ concentrations for dating.

85
86 Dissolved hydrocarbon samples were collected via the direct-fill method in 60-mL VOA vials
87 with Teflon-lined septa and preserved with 1:1 HCl to a pH <2. The direct-fill method from
88 Waterloo 401 sampling tubing likely leads to underestimation of methane concentrations near
89 methane saturation level at atmospheric pressure (25-30 mg/L) as there is no option to use a
90 back-pressure regulator in this system (15). Therefore, the decrease in pressure from formation
91 depth to the surface may allow for degassing of methane from saturated samples. Processing of
92 samples by creating headspaces and transferring the headspace to exetainers was accomplished
93 <7 days after collection. Filled exetainers were stored in water prior to analysis. Total and
94 dissolved metals and cation samples were collected in 125-mL HDPE bottles and preserved with
95 1% 1:1 HNO₃. Dissolved metal and cation samples were filtered using an in-line filter and 0.45
96 μm filter membrane. Anion samples were also filtered in-line using a 0.45 μm membrane, and
97 frozen. Dissolved inorganic carbon and dissolved organic carbon samples were collected in glass
98 vials without headspace and in-line filtered using a 0.2 μm membrane.

99 Methane and ethane concentrations were determined using a modified version of RSK-175
100 standard operating procedure (16, 17). The procedure was modified in that there was a 20-mL
101 headspace added to the 60-mL VOA vial. Headspace samples were then analyzed using GC-FID.
102 Samples found to have a dissolved methane concentration ≥ 0.01 mg/L were sent to UC Davis
103 Stable Isotope Facility for analysis of $\delta^{13}\text{C-CH}_4$ and $\delta^2\text{H-CH}_4$. In some cases, where results
104 warranted it, lower [CH₄] samples were sent for $\delta^{13}\text{C-CH}_4$, but results could not always be
105 obtained for these lower concentrations. Samples with ≥ 0.001 mg/L ethane were analyzed for
106 $\delta^{13}\text{C-C}_2\text{H}_6$ by Woods Hole Isotope Laboratories. Anion concentrations were determined using
107 suppressed ion chromatography. Cation and iron analyses were performed using ICP-OES, and
108 trace metals concentrations were determined using standard addition method (18) with ICP-MS.
109 Strontium isotopes were measured on a Thermo-Finnegan Multi-Collector ICP-MS, and the
110 mean $^{87}\text{Sr}/^{86}\text{Sr}$ of Standard Reference Material-987 equaled 0.71026 ± 0.000004 (SD). Water
111 isotopes were analyzed with a High Temperature Conversion Elemental Analyzer connected to a
112 Thermo Delta Plus Advantage Isotope Ratio Mass Spectrometer. Samples were analyzed along
113 with calibrated reference materials on the SMOW scale. Instrument precision is $\pm 2\text{‰}$ and $\pm 0.2\text{‰}$
114 for hydrogen and oxygen respectively. DIC and DOC concentrations were analyzed using a
115 Shimadzu TOC-V. $\delta^{13}\text{C -DIC}$ were analyzed on a GasBench II coupled to a Thermo Delta Plus
116 Advantage IRMS. $\delta^{13}\text{C -DIC}$ samples are analyzed using calibrated in house standards on the
117 PDB scale. Tritium, CFC, and SF₆ samples were analyzed by University of Miami School of
118 Marine and Atmospheric Science.

119 **Table S1.** Monitoring well topographic location and land-surface elevation; bedrock and water-table depth at monitoring wells; and
 120 sampling port depths and elevations.

132

133 **Figure S1.** Measurements of groundwater pressure at the single sampling port of MW F. See
 134 Table S1 for port elevation. The perturbation in groundwater pressure that occurred in response
 135 to top-hole drilling is circled in red.

136

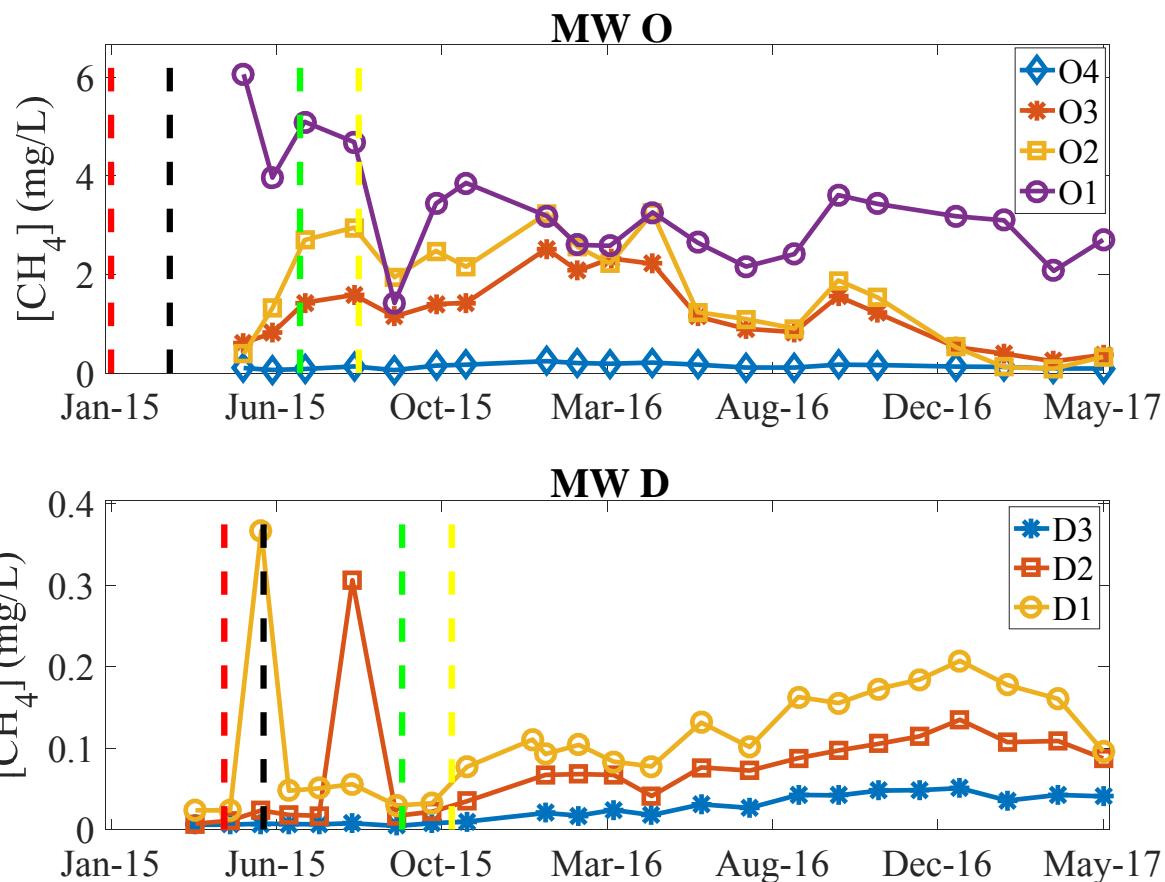

137

138 **Figure S2.** Methane concentrations ($[CH_4]$) at hilltop monitoring well R. Each solid line
 139 represents $[CH_4]$ measured in water samples collected from a particular port, numbered from
 140 deepest (R1) to shallowest (R4). See Table S1 for port elevations. The dashed red, black, and
 141 green lines respectively designate the times of top-hole drilling, horizontal drilling, and hydraulic
 142 fracturing of the gas well drilled first on the adjacent well pad, while the dashed yellow line
 143 designates the start of production (Table S2).

144

145

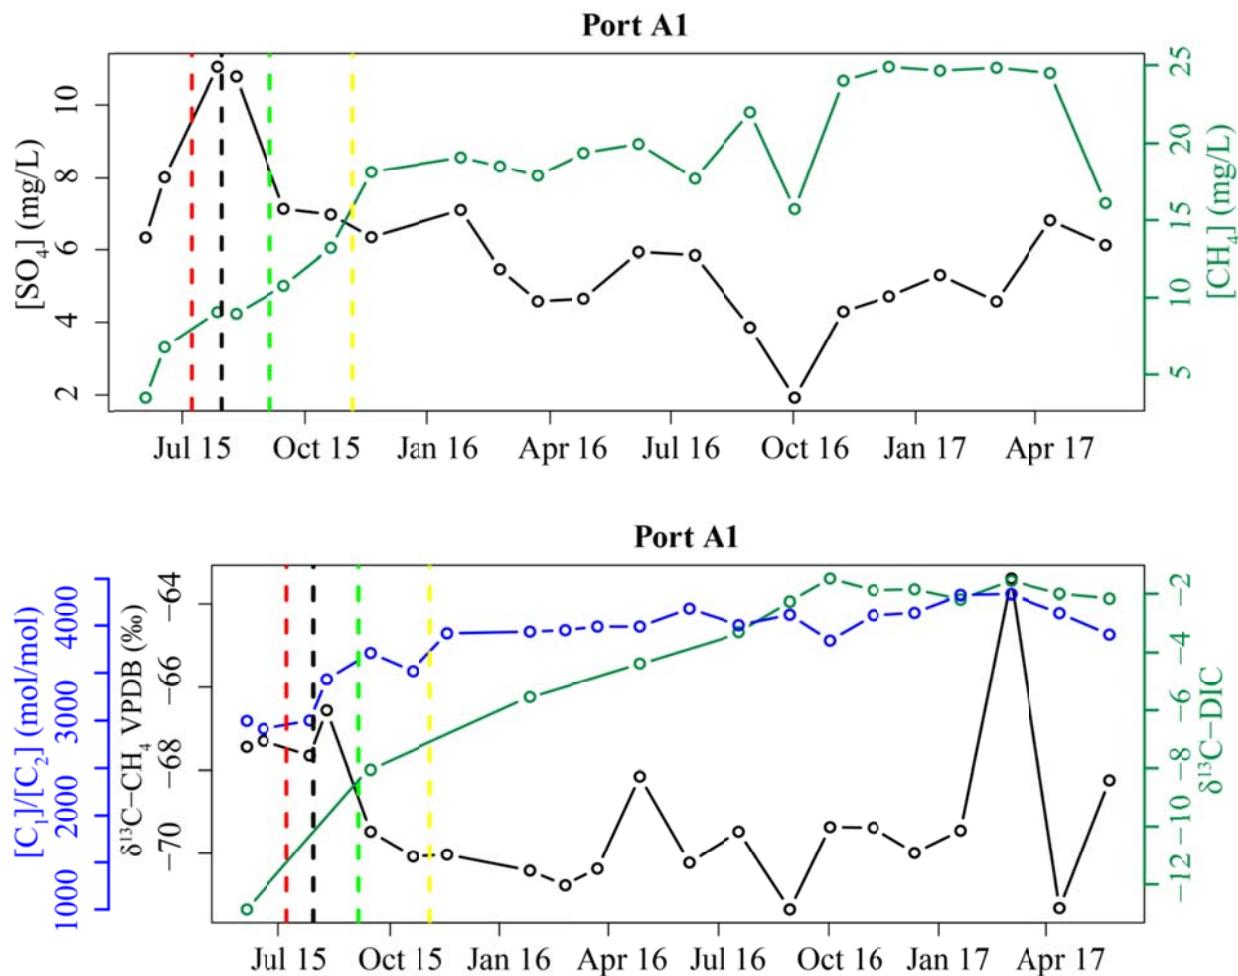

146

147 **Figure S3.** Methane concentrations ($[CH_4]$) at valley monitoring wells O and D. Each solid line
 148 represents $[CH_4]$ measured in water samples collected from a particular port, numbered from
 149 deepest (e.g., O1) to shallowest (e.g., O4). See Table S1 for port elevations. The dashed red,
 150 black, and green lines respectively designate the times of top-hole drilling, horizontal drilling,
 151 and hydraulic fracturing of the nearest underlying gas well lateral, while the dashed yellow line
 152 designates the start of production.

153

154

155

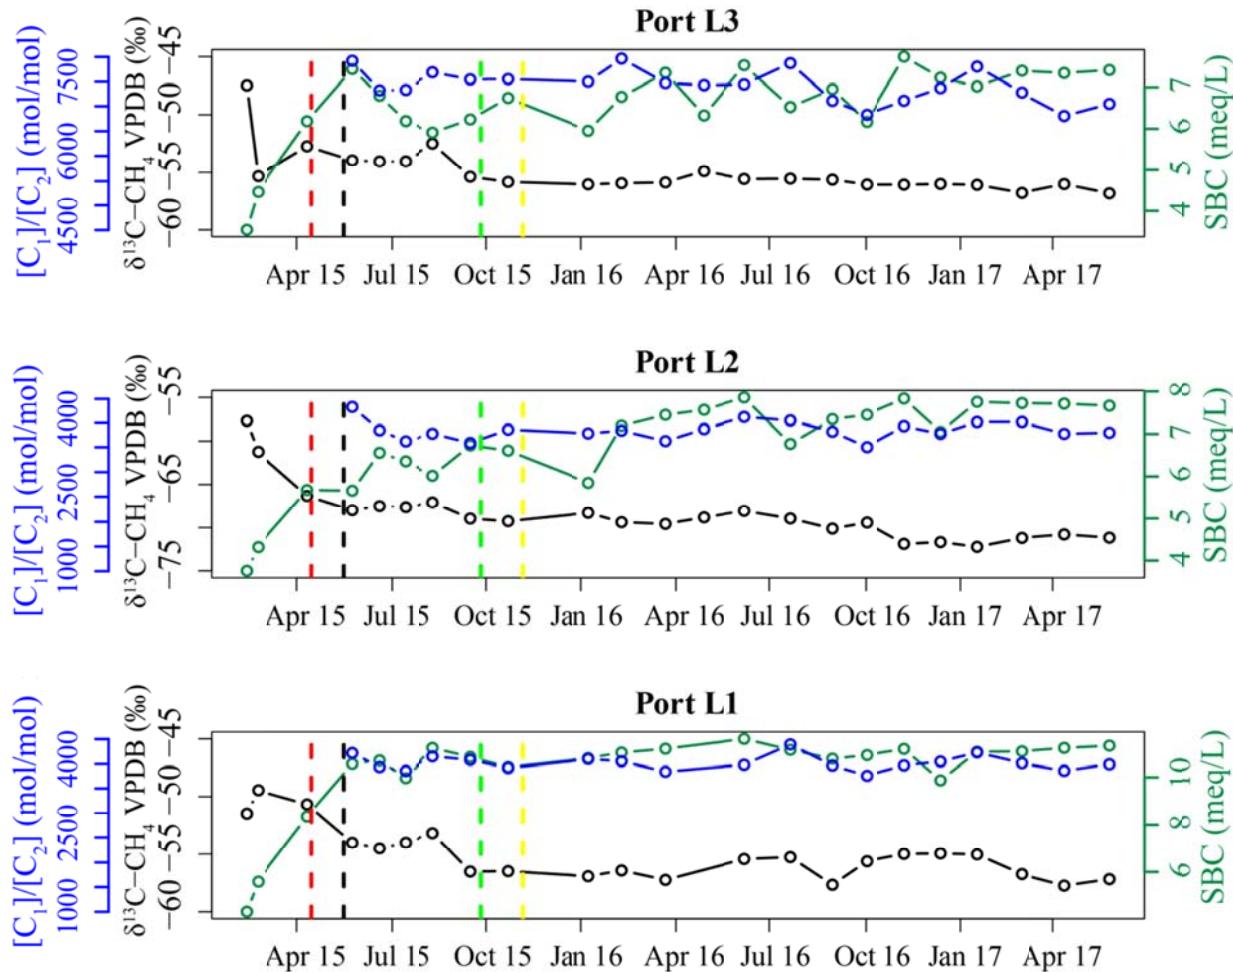

156

157 **Figure S4.** Time series measurements of $[SO_4]$ and $[CH_4]$ for the deepest port at MW A (top),
 158 and corresponding measurements of $\delta^{13}C-CH_4$, $[C_1]/[C_2]$, and $\delta^{13}C-DIC$ (bottom). The dashed
 159 red, black, and green lines respectively indicate times of top-hole drilling, horizontal drilling, and
 160 hydraulic fracturing of the nearest underlying gas well lateral, while the dashed yellow line
 161 designates the start of production.

162

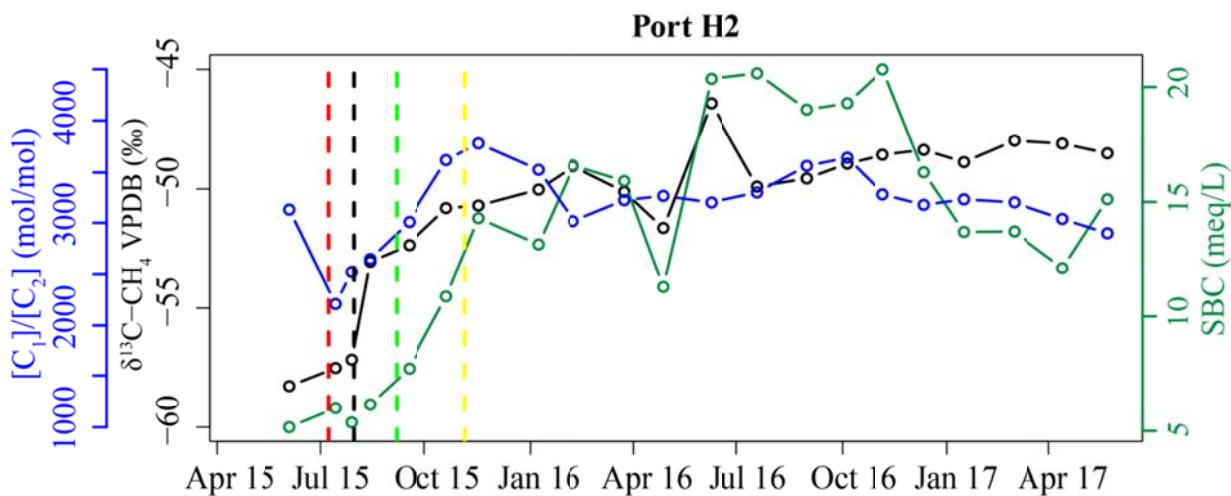

163
164

165
166 **Figure S5.** Time-series measurements of $\delta^{13}\text{C}-\text{CH}_4$, $[\text{C}_1]/[\text{C}_2]$, and salinity (as sum of the base
167 cations (SBC); Ca, Mg, Na, K) at the three deepest ports in valley well L. The dashed red, black,
168 and green lines respectively designate the times of top-hole drilling, horizontal drilling, and
169 hydraulic fracturing of the nearest underlying gas well lateral, while the dashed yellow line
170 designates the start of production. The sum of base cations constituted $\geq 99\%$ of positive charge
171 in groundwater samples.

172

173

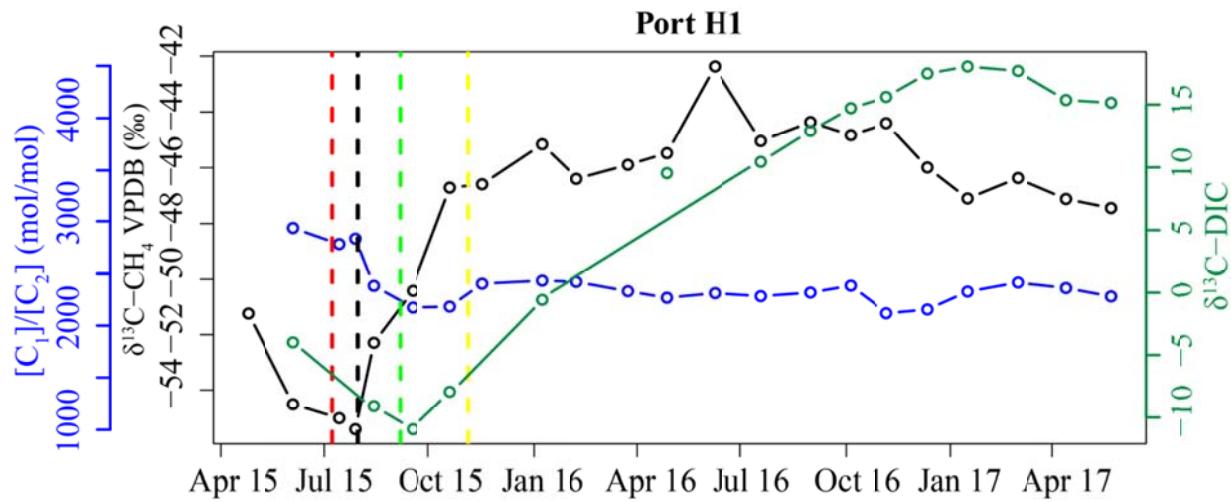

174

175

176 **Figure S6.** Time-series measurements of $\delta^{13}\text{C}-\text{CH}_4$, C_1/C_2 , and salinity (as sum of the base
 177 cations (SBC); Ca, Mg, Na, K). The dashed red, black, and green lines respectively designate the
 178 times of top-hole drilling, horizontal drilling, and HVHF of the nearest underlying gas well
 179 lateral, while the dashed yellow line designates the start of production (Table S2). The sum of
 180 base cations constituted $\geq 99\%$ of positive charge in groundwater samples.

181

182

183 **Figure S7.** Time-series measurements of $\delta^{13}\text{C-CH}_4$, $[\text{C}_1]/[\text{C}_2]$, and $\delta^{13}\text{C-DIC}$ for the deepest port
 184 at MW H. The dashed red, black, and green lines respectively designate the times of top-hole
 185 drilling, horizontal drilling, and hydraulic fracturing of the nearest underlying gas well lateral,
 186 while the dashed yellow line designates the start of production.

187

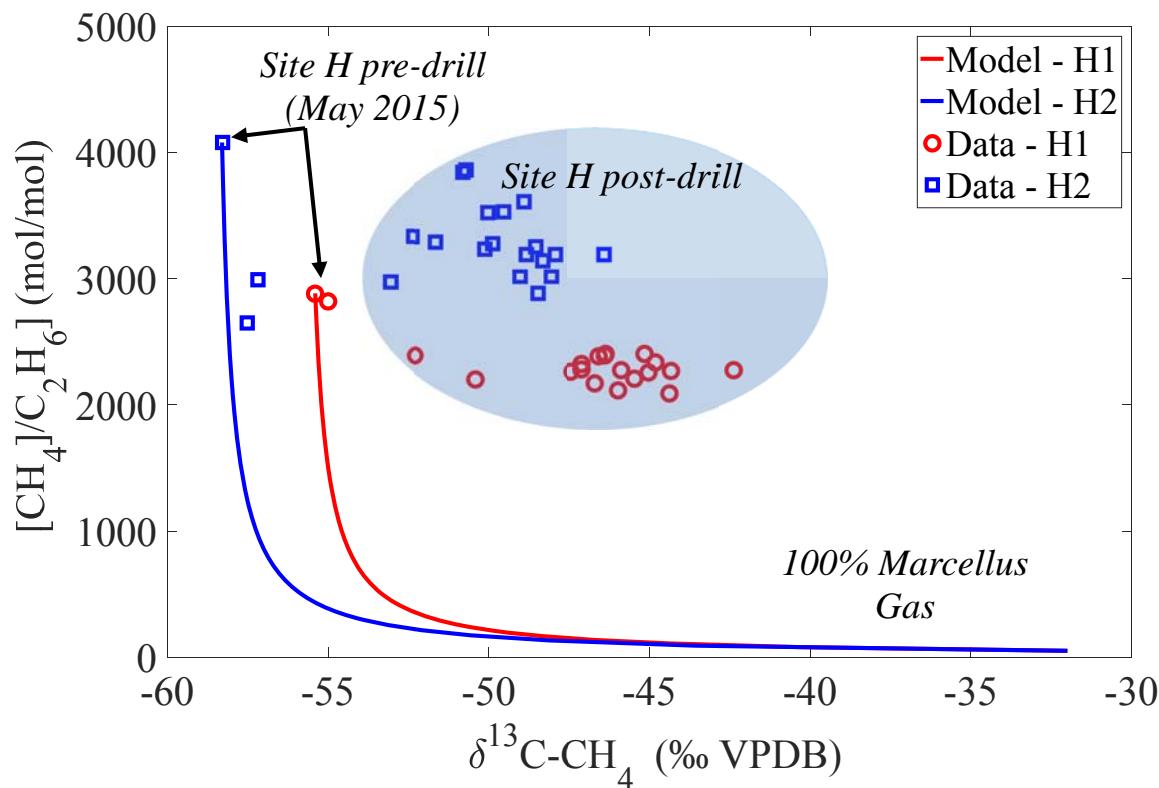

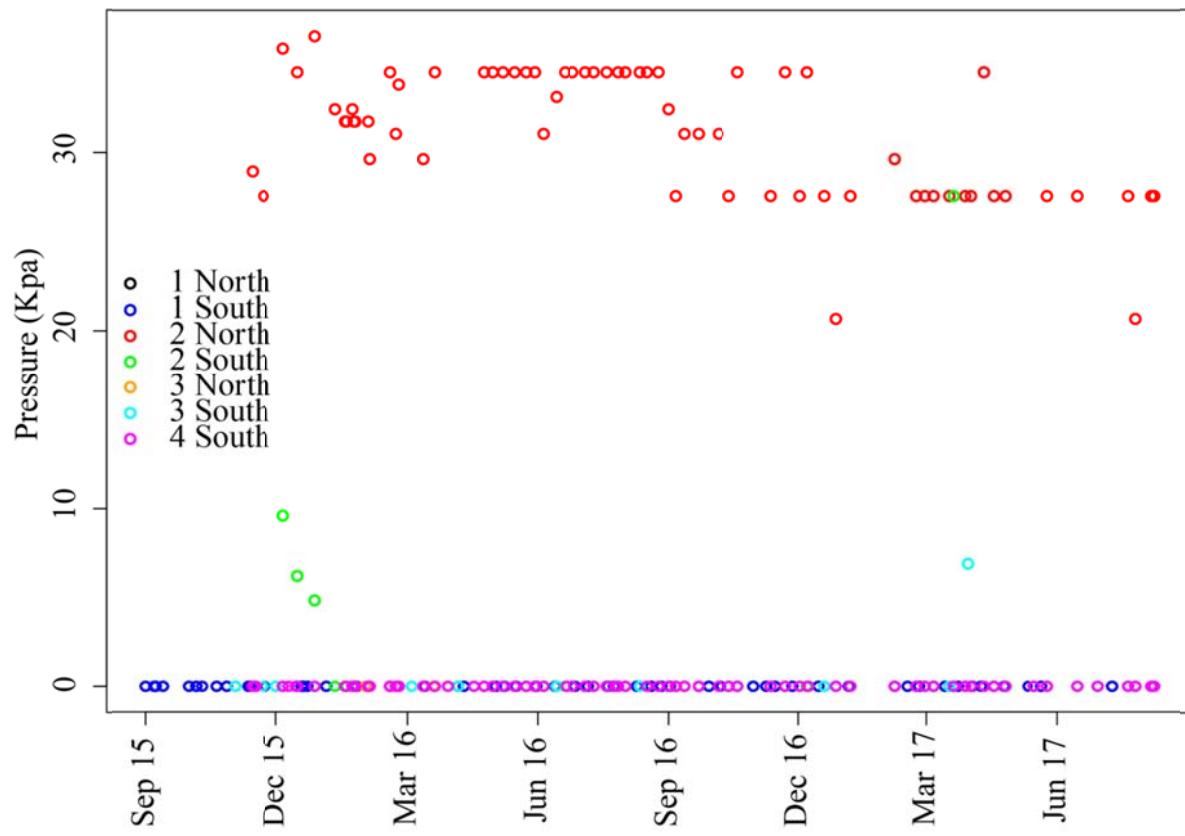

Figure S8. Measured methane-to-ethane ratio versus $\delta^{13}\text{C-CH}_4$ (symbols) and corresponding mixing-model calculations (lines) for port 1 and port 2 at MW H. The end members of the mixing model are baseline (pre-drill) samples from MW H and production gas sampled from the closest gas well. The large deviations between measured and modeled results suggests that increases in $[\text{CH}_4]$ at MW H are unlikely due to the addition of Marcellus gas.

209

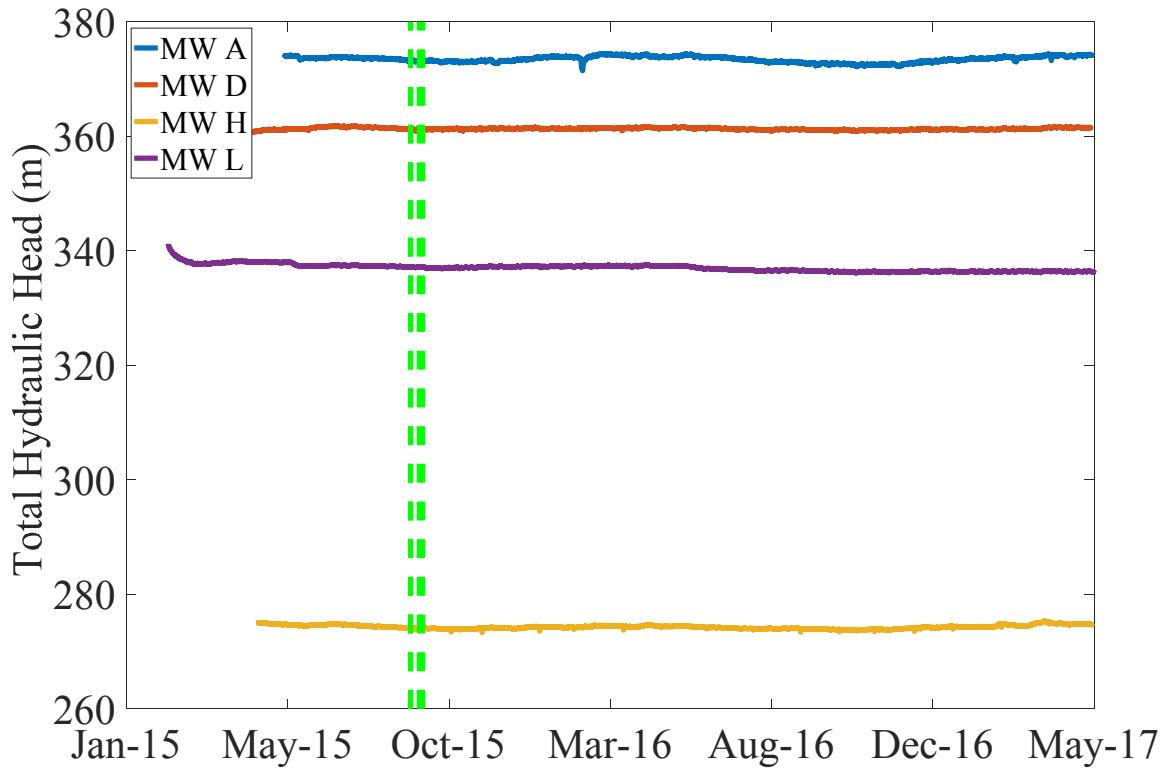

210

211 **Figure S9.** Annular pressures, measured by the operator, at the seven shale gas wells completed
 212 in the study area. Measurements were not taken at 3 South for two months when the gas well was
 213 plugged for repair following a casing rupture in which annular pressures temporarily rose to
 214 9,000 kPa.

215

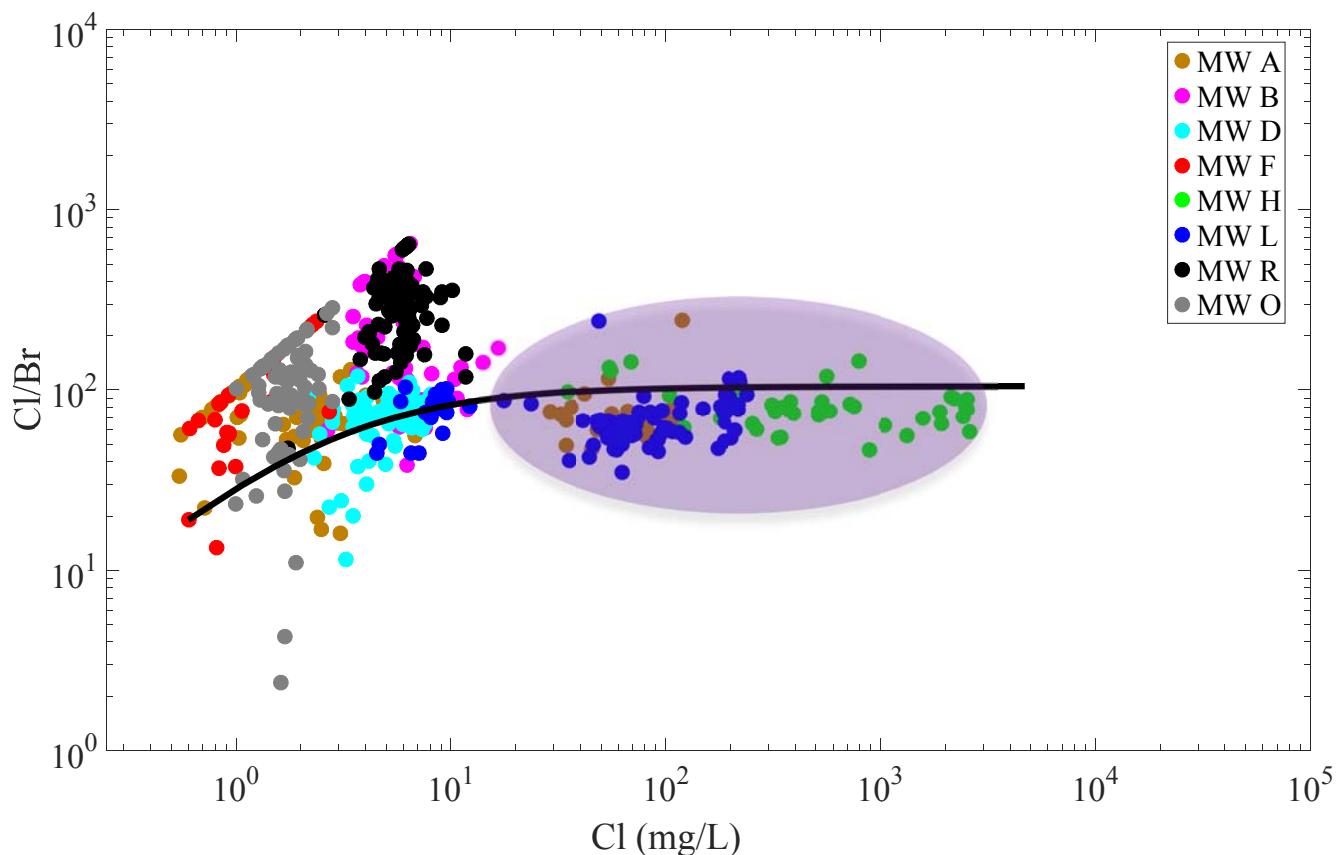

216

217

220 **Figure S10.** Hydraulic heads measured in the deepest port (port 1) of monitoring wells A, D, H,
 221 and L. The laterals of the four gas wells that underlie MWs A, D, H, and L were hydraulically
 222 fractured during the interval bracketed by the dashed green lines. Hydraulic heads within a port
 223 show little variation, which is indicative of steady groundwater flow.

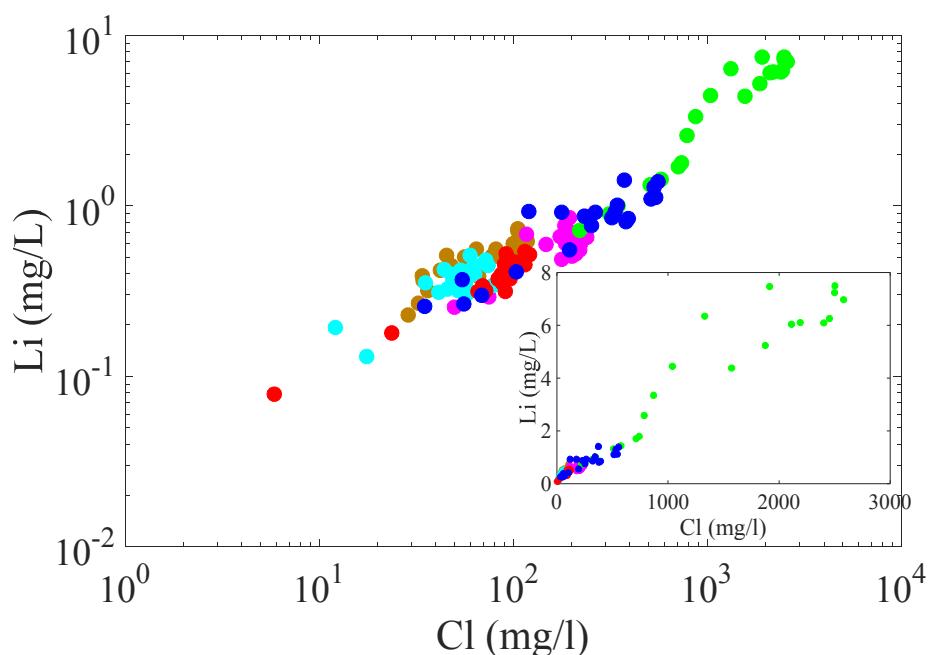

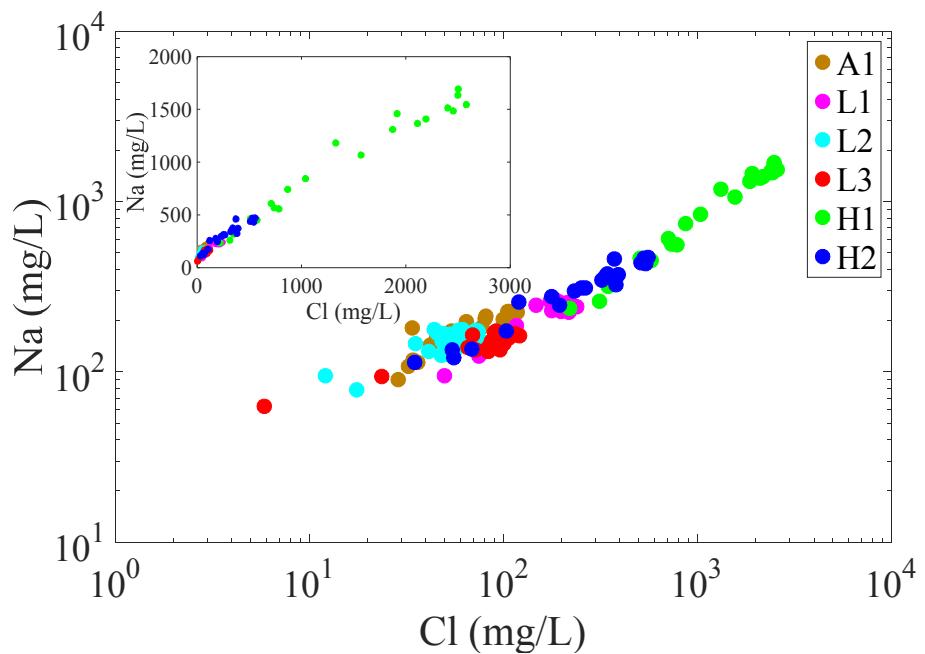

225

226

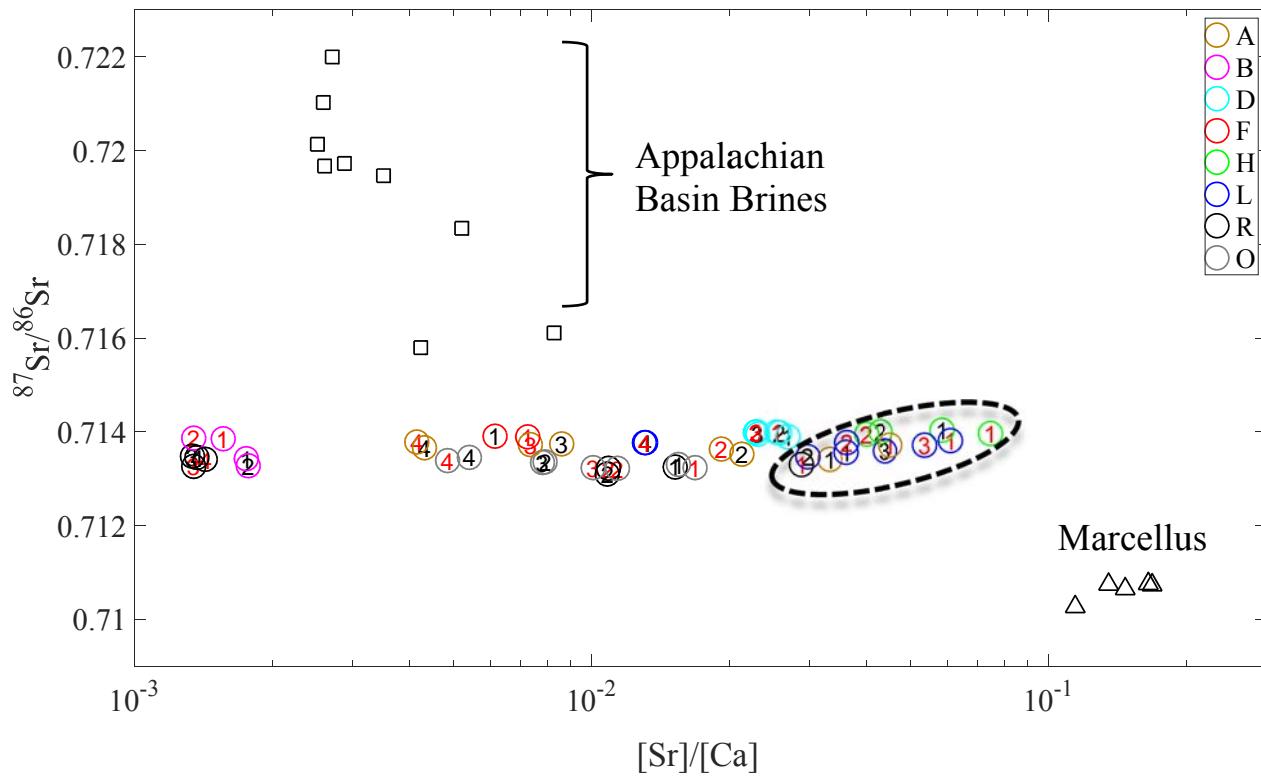

Figure S11. Measured Cl to Br mass ratios (symbols) and a two-end-member mixing curve (black line). Valley-well samples from ports A1, H1, H2, and L1-L3, where median $[CH_4]$ exceeded 5 mg/L, are enclosed by the ellipse. These samples fall near the curve computed by mixing an Appalachian Basin Brine (ABB) with dilute groundwater from site F, a hilltop site located within an aquifer recharge area. Concentrations of Br and Cl for the ABB end member were set equal to those of a brine-containing sample from Salt Springs State Park, Susquehanna County, PA (19). Samples forming the straight line in the northwest corner of the plot represent minimum $[Cl]/[Br]$ because $[Br]$ in these samples were below the detection limit (0.01 mg/L).

235

238 **Figure S12.** Concentrations of Na and Li versus concentrations of Cl (log-log scale) for valley-
 239 well samples from ports A1, H1, H2, and L1-L3. Insets show relationships on a linear scale.
 240 These linear relationships, together with the [Cl]/[Br] as depicted in Figure S11, are consistent
 241 with conservative mixing associated with dilution of an ABB.

242

243

244 **Figure S13.** $^{87}\text{Sr}/^{86}\text{Sr}$ versus strontium-to-calcium molar ratio for groundwater collected in June
 245 2015 prior to HVHF (circles with black port numbers) and in June 2016 after HVHF (circles
 246 with red port numbers). Marcellus brine (Bradford County, PA) (20) and Appalachian Basin
 247 brines from upper Devonian formations (Venango Group, Bradford Group, Organic-rich shale)
 248 (9, 21) are represented by triangles and squares, respectively. Samples enclosed by the ellipse
 249 were collected from valley MWs and have $[\text{Sr}]/[\text{Ca}]$, $^{87}\text{Sr}/^{86}\text{Sr}$, $[\text{Cl}]$, and $[\text{Br}]/[\text{Cl}]$ characteristic
 250 of shallow groundwaters that possibly contain small proportions (<1%) of Marcellus brine (9).
 251 The small differences in $[\text{Sr}]/[\text{Ca}]$ and $^{87}\text{Sr}/^{86}\text{Sr}$ between pre- and post-HVHF samples suggest
 252 that HVHF did not increase the proportion of Marcellus brine within any of the MWs.

253

254

255

Table S4. Tabulated results for major anions, major cations, methane, ethane, hydrocarbon isotopes, Li, Sr, and DIC isotopes in 542 groundwater samples. Detection limits are 0.002 and 0.0004 mg/L for methane and ethane, respectively.

256
