Neuropsychological assessment

Participants completed a neuropsychological test battery, which cover a rage of clinically important neurocognitive domains. Relevant for the present study is current IQ which was measured with the Wechsler Abbreviated Scale of Intelligence (WASI) (1). For details, see (2).

Clinical assessment

Patients went through symptoms assessment (The Positive and Negative Syndrome Scale (PANSS)(3)) and a thorough interview mapping diagnosis, history of disorder, age at onset, hospitalisation, pharmacological treatment and substance use. Psychosocial functioning was assessed with split version of Global Assessment of Functioning Scale (GAF)(4). Trained clinical psychologists and physicians performed clinical, cognitive and diagnostic assessments. For more information, see (5).

Interview at the day of scanning

At the day of scanning, the session started with a short interview and a urine sample to screen for drugs. Patients were asked about recent use of alcohol, drugs and medications, and changes in symptoms since the clinical interview. HCs were asked about recent use of alcohol, drugs and medications, and screened with the Primary Care Evaluation of Mental Disorders (PRIME-MD) (6).

Quality Control

After exclusion, there was a significant group difference for the QC sum score (SZ/BD/HC: -0.13/-0.15/0.08; F= 3.67, p>.026). Compared to HC and BD, SZ showed higher MAXVOX (2201/1775/1799; F= 5.08, p<.009), and BD had higher tSNR relative to HC (8.85/7.74/8.88; F= 3.78, p<.024). Summary stats for the DTI metrics at each QC step are presented in Supplemental Table S5, while Summary Table S6 presents a demographic overview of the participants excluded at each QC step. The excluded participants were visually inspection in order to also manually assess QC. Density plots of DTI metrics within groups for the entire sample (A), for the sample after exclusion of datasets based on quality control and the excluded participants from the quality control are presented in Supplemental Figure S13. In addition, we carried out voxelwise analysis of FA, MD, RD and AD on

the participants that survived the most stringent QC cutoff. The voxel-wise analyses prior to and after QC are presented in Figure 1 and Supplemental Figure S8.

Associations with symptom domains

In line with previous research (7-9) we found no significant associations between WM integrity measures (FA, RD, MD, and AD) and disease severity measured using GAF/PANSS symptom domains. Whereas this lack of sensitivity of DTI metrics to clinically relevant variability does not support a simple dimensional model, it may also suggest the descriptive clinical variables are not readily interpretable or suitable in a dimensional framework targeting mechanisms of disease. Further refinements of both imaging and clinical variables are needed, and further pursuits within a systems neuroscience framework may provide a sensible conceptual and methodological context for improving our understanding of the brain processes underlying complex behaviors and disorders (10).

Diagnostic subgroups

The two major diagnostic groups (SZ and BD) comprise of diagnostic subgroups that might increase the heterogeneity with the groups. Due to the small sample size within some of the subgroups (BD NOS, SA, and SFF) it was not feasible to compare them with the other subgroups within its own spectrum. The results are presented in Supplemental Table S3 and Supplemental Figure S10.

Supplemental Figure S1.

Age distribution within each group, healthy controls (HC), bipolar disorder (BD) and schizophrenia (SZ).

Supplemental Figure S2.

The histogram depicting the empirical null distribution for each contrast generated using permutation testing across 10 000 iterations with the 95% confidence intervals (in grey). The observed age difference between groups is also plotted.

Supplemental Figure S3.

The age when the maximum peak of FA for mean skeleton and 23 regions of interest plotted for each group, healthy controls (HC), bipolar spectrum (BD) and schizophrenia spectrum (SZ). The age estimates were generated from a bootstrap resampling procedure with 10000 iterations. Abbreviations: Superior longitudinal fasciculus (SLF), Inferior longitudinal fasciculus (ILF), Inferior fronto-occipital fasciculus (IFOF), and Anterior thalamic radiation (ATR).

Supplemental Figure S4.

The age when the minimum peak of RD for mean skeleton and 23 regions of interest plotted for each group, healthy controls (HC), bipolar spectrum (BD) and schizophrenia spectrum (SZ). The age estimates were generated from a bootstrap resampling procedure with 10000 iterations. Abbreviations: Superior longitudinal fasciculus (SLF), Inferior longitudinal fasciculus (ILF), Inferior fronto-occipital fasciculus (IFOF), and Anterior thalamic radiation (ATR).

Supplemental Figure S5.

The age when the minimum peak of MD for mean skeleton and 23 regions of interest plotted for each group, healthy controls (HC), bipolar spectrum (BD) and schizophrenia spectrum (SZ). The age estimates were generated from a bootstrap resampling procedure with 10000 iterations. Abbreviations: Superior longitudinal fasciculus (SLF), Inferior longitudinal fasciculus (ILF), Inferior fronto-occipital fasciculus (IFOF), and Anterior thalamic radiation (ATR).

Supplemental Figure S6.

The age when the minimum peak of AD for mean skeleton and 23 regions of interest plotted for each group, healthy controls (HC), bipolar spectrum (BD) and schizophrenia spectrum (SZ). The age estimates were generated from a bootstrap resampling procedure with 10000 iterations. Abbreviations: Superior longitudinal fasciculus (SLF), Inferior longitudinal fasciculus (ILF), Inferior fronto-occipital fasciculus (IFOF), and Anterior thalamic radiation (ATR).

Supplemental Figure S7.

A window of 150 participants in steps of 5 participants were slid along the sorted age span. The resulting Cohens d and t-values resembling pairwise group differences are plotted against the mean age of each sliding group.

Supplemental Figure S8.

Heat map generated from mean skeleton and ROI analyses reflecting t-values for GAF and PANSS symptom domain scores with the nominal p-values overlaid. No associations were significant when p was corrected using false discovery rate (FDR))(11).

Supplemental Figure S9.

Voxel-wise analyses on participants surviving the most stringent QC step (n=447). Coloured voxels show significantly decreased (blue) and increased (red) DTI-indices in SZ patients relative to HC and BD. Group differences are thresholded at p < .05 (two-tailed) after permutation testing using threshold free cluster enhancement (TFCE). Note that the white matter skeleton has been slightly thickened to aid visualisation.

Supplemental Figure S10.

Density plots of mean skeleton DTI metrics for the subgroup of schizophrenia spectrum disorders (A) and bipolar disorders (B). AD, MD and RD are multiplied by 1 000 000 to preserve precision.

Supplemental Figure S11.

Density plot of the tSNR distribution comparing two versions of Eddy, one with a slice replacement option (eddy_prepol) and one without (eddy).

Supplemental Figure S12.

Overview of the quality control procedure, and number of excluded participants at each step. In an iterative fashion, subjects with a QC sum z-score below -2.5 were excluded, and the group statistics were recomputed. This was repeated until no datasets had a z-score below -2.5.

Supplemental Figure S13.

Density plots of DTI metrics within groups for the entire sample (A), for the sample after exclusion of datasets based on quality control (B) and the excluded participants from the quality control (C)

Mean skeleton DTI metrics for each subgroup for each of the two diagnostic groups (SZ and BD).

Note. MD,RD,AD multiplied by 1 000 000 to preserve precision. The p-values are not corrected for multiple testing. [#]Due to small subgroup sizes, subgroup comparisons were only conducted for the HC/SZ/PNOS and the HC/BDI/BDII contrasts. The subgroups within the schizophrenia spectrum (SZ) were: schizophrenia (SZ), schizoaffective (SA), schizophreniform (SFF) and psychosis not otherwise specificed (SFF). The subgroups within the bipolar spectrum were: bipolar 1 disorder (BDI), bipolar 2 disorder (BDII) and bipolar disorder not otherwise specificed (BDNOS).

Note. Subjects with a QC sum z-score below -2.5 were excluded, and the group statistics were recomputed. This was repeated until no datasets had a z-score below -2.5. In total there were six rounds of exclusion before no datasets had a z-score below -2.5. n482 is the complete dataset, n471 is the first round of exclusion and the subsequent reduction of number of participants (n471, n462, n457, n453, n448, n447) indicates the successive rounds of exclusions.
