Supplementary Results Appendix

Forecasting life expectancy, years of life lost, all-cause and cause-specific mortality for 250 causes of death: reference and alternative scenarios 2016–2040 for 195 countries and territories

List of Figures and Tables

Figure 1. Swarm plots showing the annualized effect of each covariate on the predicted change in mortality from 2017 to 2040. Where possible, models were fit with a linear spline on SDI with a knot at 0.8 - this is reflected by the two separate SDI columns in many cause-sex pairs. The coefficients for each SDI category only impact mortality for location-years where the SDI falls within that category. Thus, countries with SDI below 0.8 through the entire forecast time series will have non-zero swarm plot values only in the 'SDI < 0.8' column. Likewise, locations with SDI above 0.8 through the time series will only have non-zero swarm plot values in the 'SDI \geq 0.8' column. Locations with forecast SDI values in both categories will have non-zero swarm plot values in both columns. Secular trend effect is shown as the average effect taken over ages. Each data point represents a location and is color coded by GBD 2016 super region. Blue = Southeast Asia, East Asia, Oceania. Orange = Central Europe, Eastern Europe, Central Asia. Green = High Income. Red = Latin America and Caribbean. Purple = North Africa and Middle East. Brown = South Asia. Pink = Sub-Saharan Africa. SDI = Sociodemographic Index. (Page 3)

Figure 2. Illustration of the components of the mortality modeling process for all-cause mortality for females in Australia. The panels on the left show cause-specific death rates by age, with small multiples showing the time trend from 1990 to 2040 for each age group. The bottom left panel is the underlying mortality component captured by SDI and global secular trends; above that is risk-attributable mortality, captured by the risk factor scalar; second from the top is the sum of the underlying and risk-attributable mortality; and the top left panel shows the final mortality predictions after the ARIMA process, which accounts for latent trends. The panels on the right show the cause- and risk-specific population attributable fractions (PAFs) that go into the risk attributable estimation; the all-risk PAF at the top is used to create the risk factor scalar, and the specific risks are then sorted in descending order of attributable deaths in 2016. (Page 57)

Figure 3. Ten leading risk factors contributing to the difference in YLLs between the forecast and worse health scenario in 2040 by location, representing potential burden with regression to the worse scenario for each risk factor. Values are reported in thousands, with 95% uncertainty intervals in parentheses. YLLs = years of life lost. (Page 58)

Figure 4. Global life expectancy from 1990-2040 in the reference scenario (forecast), better health, and worse health scenarios. Dashed lines represent global male life expectancy, solid lines represent global female life expectancy. Black lines = past data from GBD 2016. Blue = reference scenario. Green = better scenario. Red = worse scenario. Shaded areas represent 95% uncertainty intervals. (Page 68)

Figure 5. Difference between the better and worse life expectancy scenarios in 2040 for both sexes combined. Legend measured in years. *Summary:* Based on the potential trajectories of many independent drivers (ie, risk factors, SDI, and coverage of interventions like ART and vaccination) and their substantive effects on life expectancy, we forecasted gains in survival that could span from nearly 3

years in Japan to more than 20 years in South Africa. In higher-income countries, this range was generally bounded to a 3–4 year gain, even for the better scenario. Conversely, modifying trajectories of independent drivers could result in life expectancy improvements of at least four years in much of sub-Saharan Africa; among locations with large HIV epidemics, such advances could easily exceed 10 years by 2040. ATG=Antigua and Barbuda. BRB=Barbados. COM=Comoros. DMA=Dominica. E Med=Eastern Mediterranean. FJI=Fiji. FSM=Federated States of Micronesia. GRD=Grenada. KIR=Kiribati. LCA=Saint Lucia. MDV=Maldives. MHL=Marshall Islands. MLT=Malta. MUS=Mauritius. SGP=Singapore. SLB=Solomon Islands. SYC=Seychelles. TLS=Timor-Leste. TON=Tonga. TTO=Trinidad and Tobago. VCT=Saint Vincent and the Grenadines. VUT=Vanuatu. W Africa=West Africa. WSM=Samoa. (Page 69)

Table 1. Number of Years of life lost (YLLs) and deaths in GBD 2016, the 2040 forecast (reference scenario), better, and worse scenarios for all causes of death and all locations. Values are reported as counts, or in thousands, as described in the location specific heading, and 95% uncertainty intervals are in parentheses. Due to differences in populations and SDI across the scenarios, forecasts of numbers (and not rates) may result in reference values outside of the better and worse estimates. Highlighted rows indicate level 1 and 2 causes from the GBD cause hierarchy. GBD = Global burden of disease. (Page 70)

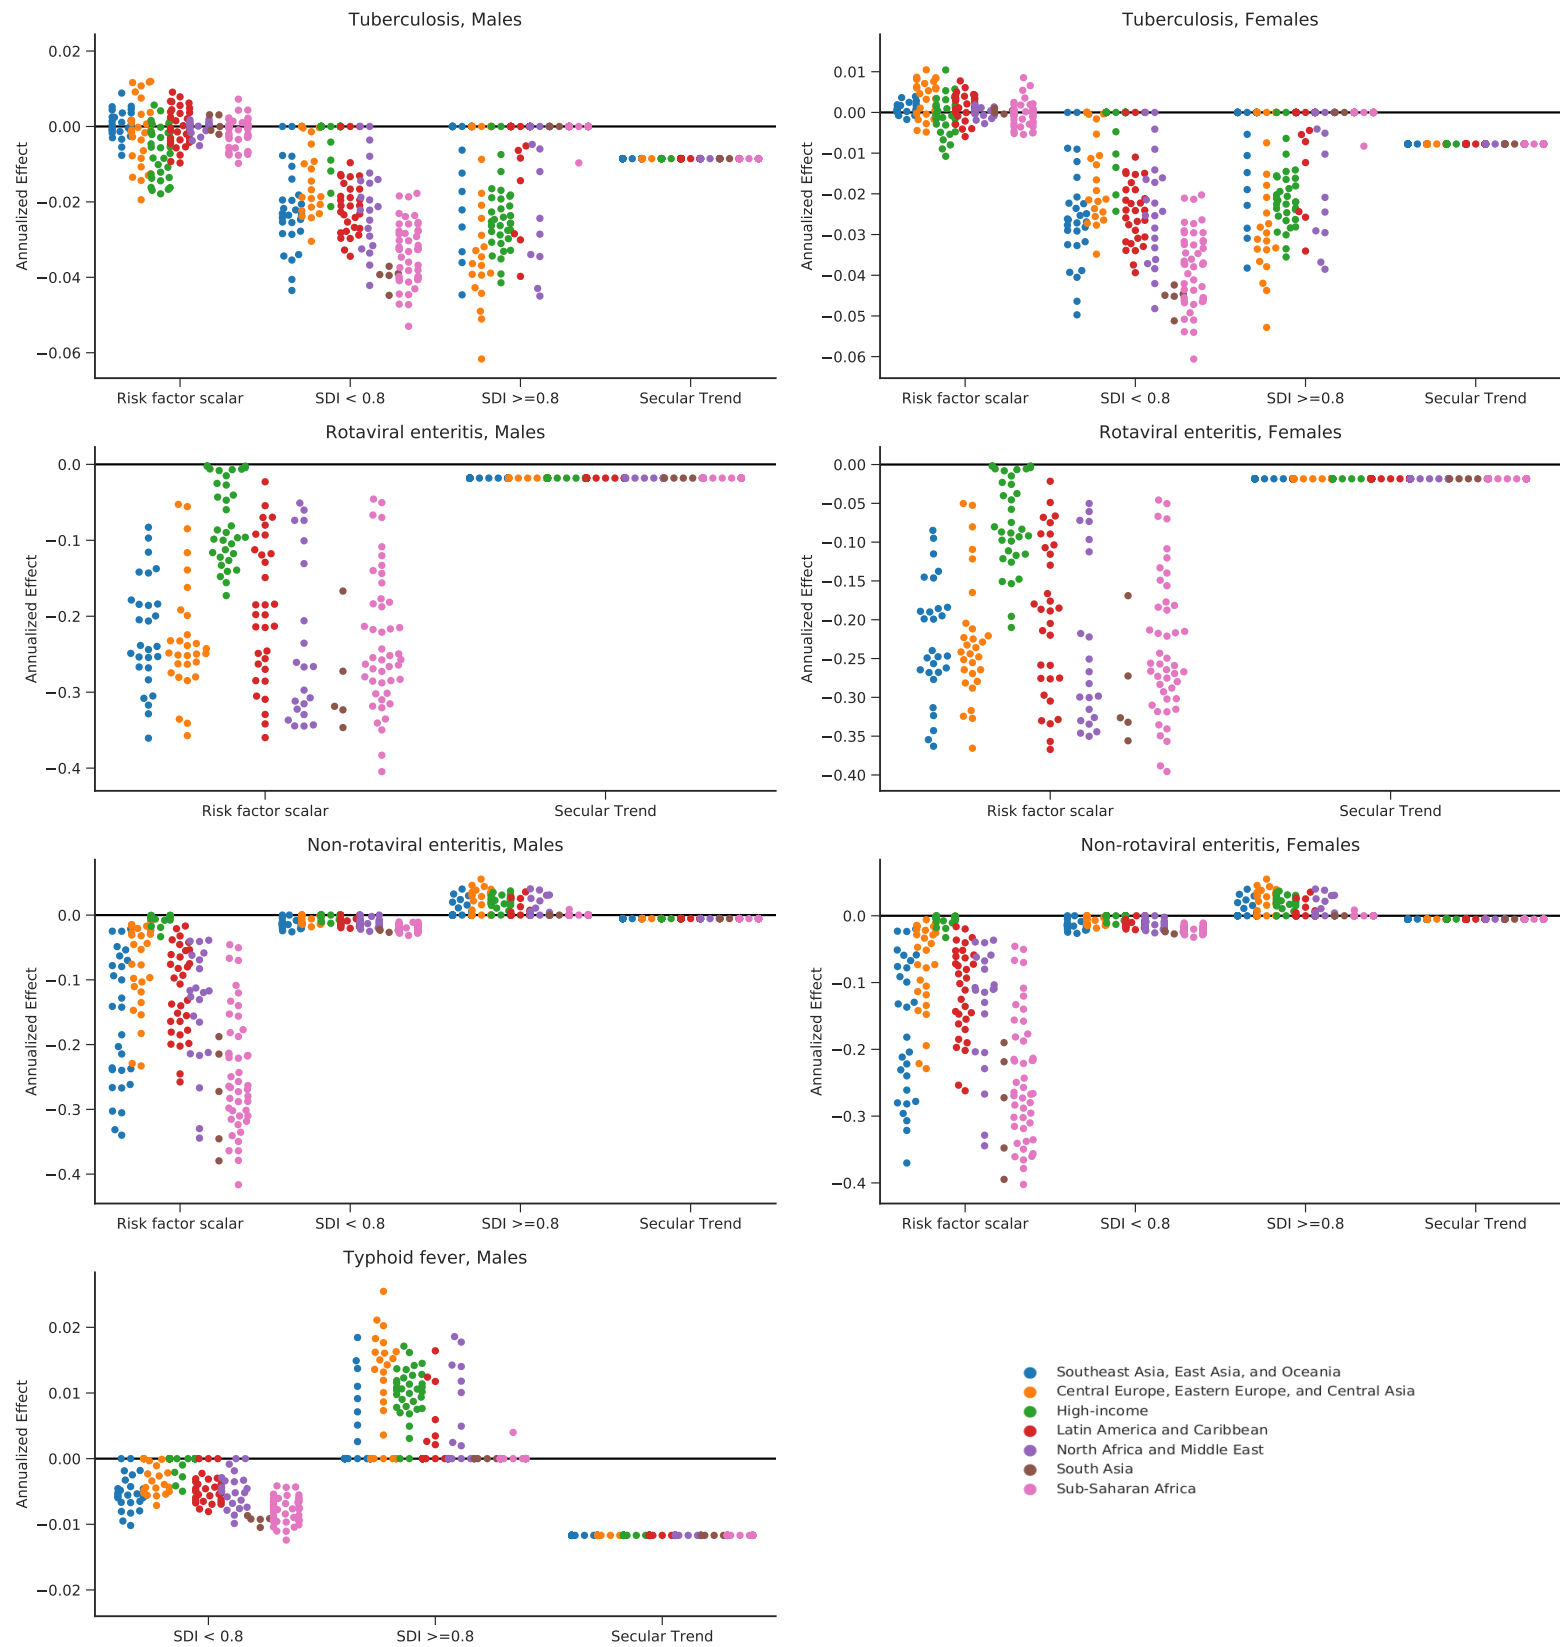

Table 2. Correlation between SEV_{rc} and SEV_r in the period 1990-2016. Values were computed as Pearson correlation coefficients. SEV = summary exposure variable. (Page 3,649)

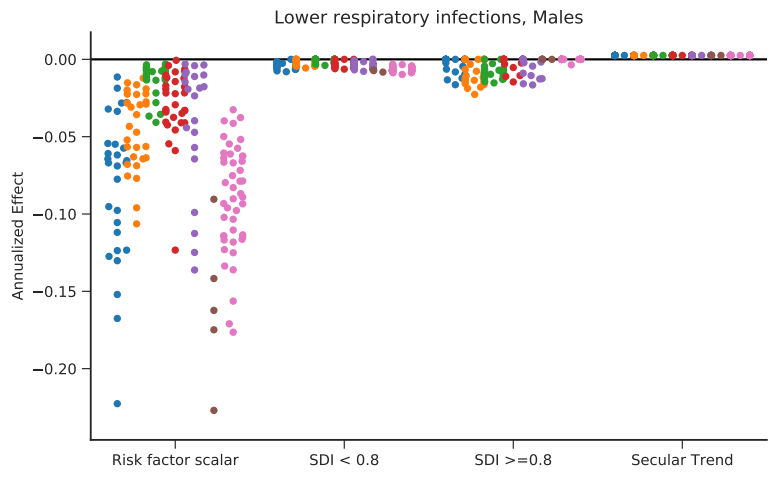

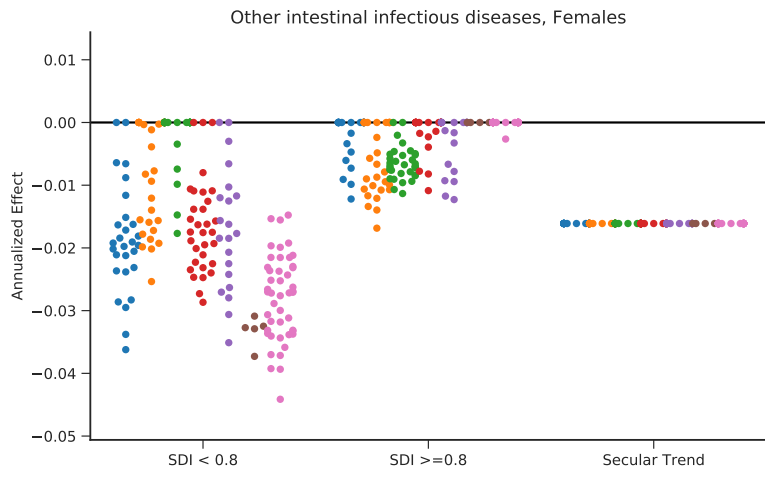

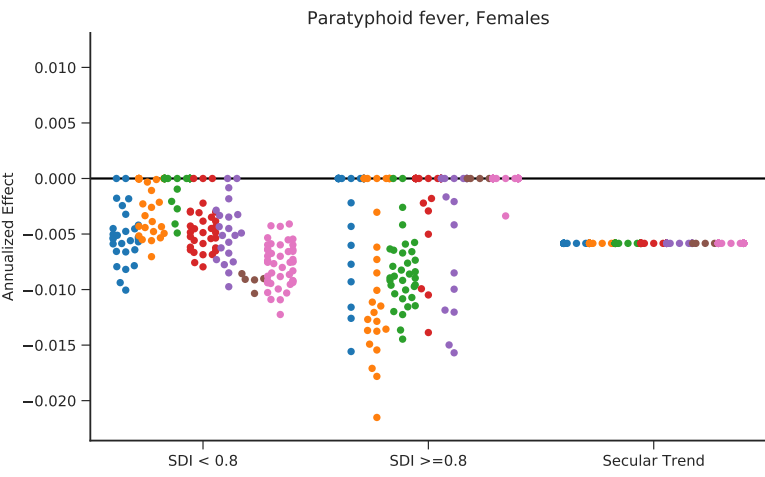

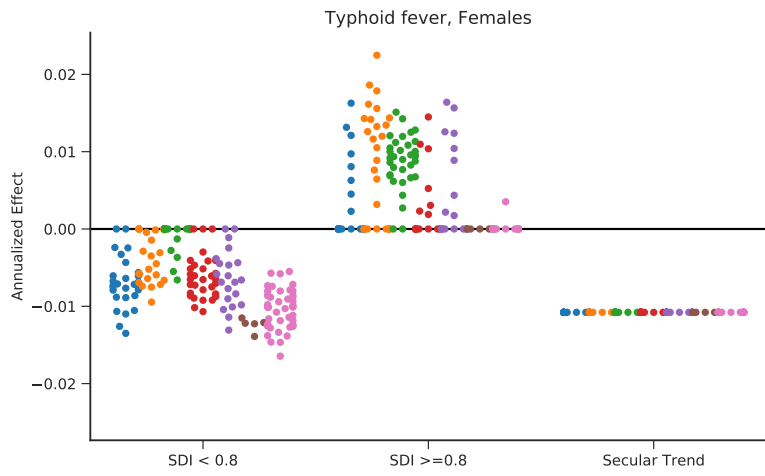

Table 3a. Pearson correlation coefficients among the components of SDI, top 20 risks, and vaccines in GBD 2016 for 1990-2016. Blank cells occur where risk pairs are not estimated on overlapping age groups. (Page 3,659)

Table 3b. Pearson correlation coefficients among the components of SDI, top 20 risks, and vaccines in reference scenario forecasts 2017-2040. Blank cells occur where risk pairs are not estimated on overlapping age groups. (Page 3,660)

Table 3c. Ratio of correlation coefficients among the components of SDI, top 20 risks, and vaccines in reference scenario forecasts (2017-2040) divided by correlations in the past (1990-2016). (Page 3,661)

Supplemental Results Appendix Figure 1. Swarm plots showing the annualized effect of each covariate on the predicted change in mortality from 2017 to 2040. Where possible, models were fit with a linear spline on SDI with a knot at 0.8 - this is reflected by the two separate SDI columns in many cause-sex pairs. The coefficients for each SDI category only impact mortality for location-years where the SDI falls within that category. Likewise, locations with SDI above 0.8 through the time series will only have non-zero swarm plot values in the 'SDI >= 0.8' column. A subset of causes also include coefficients for the SDI*Time interaction term. See the methods appendix (pp 9) for more details. Locations with forecasted SDI values in both categories will have non-zero swarm plot values in both columns. Secular trend effect is shown as the average effect taken over ages. Figure 2. Illustration of the components of the mortality modeling process for all-cause mortality for females in Australia. The panels on the left show cause-specific death rates by age, with small multiples showing the time trend from 1990 to 2040 for each age group. The bottom left panel is the underlying mortality component captured by SDI and global secular trends; above that is risk-attributable mortality, captured by the risk factor scalar; second from the top is the sum of the underlying and risk-attributable mortality; and the top left panel shows the final mortality predictions after the ARIMA process, which accounts for latent trends. The panels on the right show the cause- and risk-specific population attributable fractions (PAFs) that go into the risk attributable estimation; the all-risk PAF at the top is used to create the risk factor scalar, and the specific risks are then sorted in descending order of attributable deaths in 2016.

Supplemental Appendix Figure 3. Ten leading risk factors contributing to the greatest difference in risk-attributable years of life lost (YLLs) between the forecast and better health scenario in 2040 by location. Values are reported in thousands, with 95% uncertainty intervals in parentheses.

Appendix Figure 4. Global life expectancy from 1990-2040 in the reference scenario (forecast), better health, and worse health scenarios. Dashed lines represent global male life expectancy, solid lines represent global female life expectancy. Black lines = past data from GBD 2016. Blue = reference scenario. Green = better health scenario. Red = worse health scenario. Shaded areas represent 95% uncertainty intervals.

Table 1. Number of Years of life lost (YLLs) and deaths in GBD 2016, the 2040 forecast (reference scenario), better, and worse scenarios for all causes of death and all locations. Values are reported as counts, or in thousands, as described in the location specific heading, and 95% uncertainty intervals are in parentheses. Due to differences in populations and SDI across the scenarios, forecasts of numbers may result in reference values outside of the better and worse estimates. Highlighted rows indicate level 1 and 2 causes from the GBD cause hierarchy. GBD = Global burden of disease.
