Table S1. Nerve regeneration after nerve injury and reconstruction with PCL nerve guide.

Data from the initial PCL-tube study analyzed on photographs of transverse sections at different tube levels. Due to a high degree of automutilation and processing difficulties, groups are small. Values are expressed as median (min, max), and are based on the average of three observations per specimen, except for proximal and distal to the nerve injury, where the nerve was uniform. For the hollow tube, values are based on a single observation per specimen due to a shortage of sections and a uniform distribution of cells. KW= Kruskal-Wallis. Statistical significance ($p <0.05$) based on the Mann-Whitney U-test is indicated as: ^a sign. difference from group 1 (autologous nerve graft). ^t denotes that observation is based on a single specimen.
