47 Clustering
48
49

1
2
3 **Objectives:** To cluster the adherence behaviors of patients with type 2 diabetes based on their
4 beliefs in medicines and illness perceptions and examine the psychosocial, clinical and socio-
5 demographic characteristics of patient clusters.
6
7

8
9
10 **Design:** Cross-sectional study
11

12 **Setting:** A face-to-face survey was administered to patients in two family medicine clinics in the
13 Midwest, USA.
14

15
16 **Participants:** One hundred and seventy four English-speaking ≥ 20 years old adult patients with
17 type 2 diabetes who were prescribed at least one oral diabetes medicine daily were recruited
18 using convenience sampling.
19
20
21

22
23 **Primary and secondary outcome measures:** Beliefs in medicines and illness perceptions were
24 assessed using the Beliefs about Medicines Questionnaire and the Brief Illness Perceptions
25 Questionnaire respectively. Self-reported medication adherence was assessed using the Morisky
26 Medication Adherence Scale. Psychosocial correlates of adherence, health literacy and self-
27 efficacy, were measured using the Newest Vital Sign and the Self-efficacy for Appropriate
28 Medication Use respectively. Two-step cluster analysis was used to classify patients.
29
30
31

32
33 **Results:** Participants' mean age was 58.74 (SD = 12.84). The majority were female (57.5%).
34
35 Four clusters were formed (ambivalent, skeptical (non-adherent clusters), indifferent, and
36 accepting (adherent clusters)). The ambivalent cluster (n = 30, 17.2%) included low adherent
37 patients with high necessity beliefs, high concern beliefs, and high illness perceptions. The
38 skeptical cluster (n = 53, 30.5%) included low adherent patients with low necessity beliefs, but
39 high concern beliefs and high illness perceptions. Both the accepting (n = 40, 23.0%) and
40 indifferent (n = 51, 29.3%) clusters were comprised of patients with high adherence. Significant
41 differences between the ambivalent, skeptical, accepting and indifferent adherent clusters were
42

1
2
3 based on self-efficacy, illness perception domains (treatment control, coherence), and
4
5 hemoglobin A1c ($p < 0.01$).
6

7
8 **Conclusions:** Patients with diabetes in specific non-adherent and adherent clusters still have
9
10 distinct beliefs as well as psychosocial characteristics that may help providers target tailored
11
12 medication adherence interventions.
13

14 15 16 **Strengths and limitations of this study**

- 17
18 • This is the first study to use a clustering technique to allow for algorithm-based grouping
19
20 based on both beliefs in medicines and illness perceptions founded on the Extended Self-
21
22 Regulatory Model among patients with diabetes.
23
- 24
25 • This study highlighted the importance of content and theory-driven components to enable
26
27 replication of successful adherence interventions.
28
- 29
30 • This study focused on the impact of patient psychosocial factors such as their individual
31
32 perceptions of medication and illness, self-efficacy, and health literacy in the
33
34 management of diabetes.
35
- 36
37 • Convenience sample from two clinics in one state, hereby limiting the generalizability of
38
39 the study.
40
- 41
42 • The use of a self-reported measure to evaluate medication adherence, rather than
43
44 objective measures.
45
46
47
48

49 **Funding statement:** This research received no specific grant from any funding agency in the
50
51 public, commercial or not-for-profit sectors.
52

53 **Competing Interests:** The authors have no competing interests.

Introduction

Medication adherence, defined as the extent to which taking medications corresponds with recommendations by a healthcare provider is essential for treatment success.¹ Poor adherence results in increased risk of mortality, increased emergency room visits, and reduced quality of life.²⁻⁵ In general, rates of medication adherence are below 50%.⁶ However, for patients with type 2 diabetes, these rates are as low as 36%.⁷ It is estimated that a 10% improvement in diabetes medication adherence would lead to at least a 6.6% reduction in hospitalizations.⁷

Among patients with diabetes, medication adherence has been found to be influenced by psychosocial factors, such as beliefs about illness and treatment, self-efficacy and perceived control, self-regulation, and emotional states.⁸ However, the sparse studies on patients with diabetes has generated inconsistent results and does not indicate which factors mainly affect medication adherence.⁸⁻¹⁰ Of the various factors that influence medication adherence, Horne and Weinman (2002) showed that socio-demographic and clinical factors explain only a small amount of variance in medication adherence, whereas illness perceptions and patient beliefs in medicines are substantial independent predictors.¹¹ Since patient clinical and sociodemographics are difficult to change, it makes sense to focus on patient factors that are modifiable, practical for intervention, and can be addressed by health providers.

Studies based on the Extended Self-Regulatory Model show that when patients are diagnosed with an illness, they develop a pattern of beliefs about their condition and treatment, which then influences their medication adherence.¹²⁻¹⁷ The Self-Regulatory Model (also called the Common Sense Model) was developed to explain illness-related coping behaviors including adherence to treatment, based on patient perceptions of their illness.¹⁸ When research identified beliefs about treatment as proximal determinants of coping strategies such as medication

1
2
3 adherence compared with illness perceptions, Horne et al. extended the Self-Regulatory Model
4 by integrating beliefs about treatment into the original model.^{11,12} In prior research, Phillips and
5
6 colleagues suggested that patient adherence was greater when illness and treatment perceptions
7
8 were addressed or discussed during patients' medical encounter and that healthcare providers
9
10 were better able to judge patient agreement regarding the illness and treatment when patients
11
12 reported these discussions occurred.^{19,20}
13
14
15

16
17 To design feasible and useful medication adherence interventions, Horne et al originally
18
19 classified patients with chronic illnesses into four attitudinal groups (accepting, ambivalent,
20
21 skeptical, and indifferent) based on their beliefs about their treatment.²¹ While "accepting"
22
23 patients, with high necessity beliefs and low concerns had the highest medication adherence,
24
25 "skeptical" patients, with low perceived need of medications and high concerns, had the lowest
26
27 adherence levels. Other patient groups, the "ambivalent" (high necessity beliefs and high
28
29 concerns), and the "indifferent" (low necessity beliefs and low concerns) were also likely to be
30
31 non-adherent. Though medication non-adherence is a common problem among patients with
32
33 chronic illnesses, they hardly discuss this behavior with their health providers during routine
34
35 visits.²² Various available tools used to identify medication adherence are not usable in clinical
36
37 consultations because of the short time available to providers.²³ Hence, clustering patients'
38
39 adherence behavior based on their beliefs may provide a mechanism for providers to focus on the
40
41 specific belief needs of the patients in the context of their psychosocial characteristics. A
42
43
44 previous study based on the Extended Self-Regulatory Model used both illness perceptions and
45
46 beliefs in medicines to cluster patients with asthma and was able to develop the same clusters as
47
48 developed by Horne et al.²⁴ Additionally, each cluster had psychosocial characteristics that was
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 unique to them. However, further studies were needed to determine whether the four attitudinal
4
5 group structure that includes illness perceptions also holds with other chronic disease conditions.
6
7

8 The objectives of this study were to:

- 9
10 1) Cluster the adherence behaviors of patients with type 2 diabetes based on their beliefs in
11
12 medicines and illness perceptions.
13
14 2) Examine the psychosocial, clinical and sociodemographic characteristics of patient clusters.
15
16

17 This study hypothesized that patient clusters with high concern beliefs and low necessity
18
19 beliefs will also have high threatening illness perceptions, and groups with low concern beliefs
20
21 and high necessity beliefs will have low threatening illness perceptions.
22
23

24 **Methods**

25
26 Using a cross-sectional study design, a face-to-face survey was administered to English-speaking
27
28 ≥ 20 years old patients with type 2 diabetes who were prescribed at least one oral diabetes
29
30 medicine daily. Patients were recruited using convenience sampling. Information on eligible
31
32 patients were retrieved from the electronic health record database of two family medicine clinics
33
34 in a Midwestern state in the United States.
35
36

37 *Data collection*

38
39 Front desk receptionist at the two clinics provided study information sheets to eligible patients
40
41 who were waiting for their appointment. After patients reviewed the information, they met with a
42
43 research assistant to indicate their interest in participating. The research assistant verified the
44
45 patient's eligibility from the clinic's patient log, administered the informed consent form, and
46
47 completed the 20-30 minutes survey with the consented participant in a private area in the clinic.
48
49 Participants were allowed to complete the survey before or after their scheduled clinic
50
51 appointments, depending on clinic flow and their preferences. Informed consent was obtained
52
53
54
55
56
57
58
59
60

1
2
3 from all individual participants included in the study. All data collection occurred from March
4
5 2016 to August 2016. Patients were compensated with \$25 cash, upon completion of the survey.
6
7
8 The University Health Sciences Institutional Review Board approved the study.
9

10 *Measures*

11
12 Self-reported medication adherence was assessed using the 8-item Morisky Medication
13
14 Adherence Scale (MMAS-8), a widely used scale in patients with diabetes.²⁵⁻²⁹ The total score
15
16 of the MMAS-8 ranged from 0 to 8 and MMAS-8 scores of < 6, 6 to < 8, and 8 reflected low,
17
18 medium, and high medication adherence, respectively.²⁶ The 10-item Beliefs in Medicines
19
20 Questionnaire (BMQ) was used to measure patient beliefs in medications.³⁰ The BMQ includes
21
22 the necessity beliefs and concern beliefs sub-scales measured on five-point Likert-type scales
23
24 with ‘strongly disagree’ to ‘strongly agree’ response options.³⁰ The range of scores for each sub-
25
26 scale is 5-25, with a higher score meaning stronger concern beliefs or stronger necessity beliefs
27
28 about the medicine. The 8-item Brief-Illness Perceptions Questionnaire (B-IPQ) was used to
29
30 measure patients’ perceptions about diabetes.³¹ This validated instrument includes survey items
31
32 assessing patient illness perceptions about diabetes along the cognitive domains of the self-
33
34 regulatory model as well as their emotional responses to having diabetes.³¹ Each survey item of
35
36 the B-IPQ was assessed on a scale of 0-10 with higher scores indicating stronger threatening
37
38 perceptions along the illness perception dimensions.
39
40
41
42
43

44
45 Finally, we assessed other patient psychosocial correlates of medication adherence, i.e.
46
47 health literacy and self-efficacy. Health literacy assessed using the 6-item Newest Vital Sign
48
49 (NVS)^{32,33} has been extensively used across studies including patients with type 2 diabetes and
50
51 can be completed in a short time (3-5minutes).^{34,35} Each question was scored as “0” for an
52
53 incorrect response and “1” for a correct response for a total score of 0 to 6. Patients with scores
54
55
56
57
58
59
60

1
2
3 less than 2 represented a high likelihood of inadequate health literacy, 2 to 3 indicated the
4 possibility of marginal health literacy, and more than 3 suggested adequate health literacy.
5
6

7
8 Self-efficacy measured using the 13-item Self-efficacy for Appropriate Medication Use
9 Scale (SEAMS) was used in examining medication self-efficacy in chronic disease management,
10 and is appropriate regardless of patient literacy skills.^{36,37} Patients indicated under a range of
11 situations, their level of confidence regarding taking medications correctly using a 3-point Likert
12 scale (1 = not confident, 2 = somewhat confident, and 3 = very confident). The total score of the
13 SEAMS ranged from 13 to 39 with higher scores indicating more confidence in adhering to
14 medication use.³⁶
15
16
17
18
19
20
21
22
23

24 Other variables included sociodemographic factors such as age, gender, highest education
25 level, race, health insurance, and the annual household income level; patient clinical factors such
26 as the number of chronic illnesses, self-reported health status, number of medications used,
27 frequency of daily diabetes medication use, duration of diagnosis of type 2 diabetes, and whether
28 the patient used insulin or not. Besides the main predictor variables, patients' hemoglobin A1c
29 (HbA1c) values in the prior six months were retrieved from electronic medical records, with
30 lower HbA1c values $\leq 7.0\%$ representing better glycemic control. The average duration between
31 the day of the latest HbA1c testing and the day of patient completing the survey was 43.3 ± 84.6
32 days (median: 7 days).
33
34
35
36
37
38
39
40
41
42
43

44 *Data analysis*

45
46 A two-step cluster analysis was used to classify patients' medication adherence behavior based
47 on their beliefs in medicines and illness perceptions. The number of clusters to be formed was
48 kept a priori at four, a number determined by the researchers based on Horne's earlier studies
49 and our prior work.^{21,24,38-40} The cluster analysis technique organizes observed data (e.g. patients)
50
51
52
53
54
55
56
57
58
59
60

1
2
3 into meaningful groups or clusters based on combinations of the independent variables. This
4
5 process maximizes the similarity of cases within each cluster but also maximizes the
6
7 dissimilarity between the groups based on the log-likelihood distance between the data points.
8
9
10 Using this method allows the clusters to be created without a preconceived notion of what the
11
12 clusters may look like. In the first step, each data record was either considered as a new cluster or
13
14 was added to a previously formed cluster. In the second step, the clusters formed from the first
15
16 step were compared and merged based on the distance between them. Then, we assessed the
17
18 goodness of fit of the clustering solution. The silhouette measure of cohesion and separation was
19
20 used to evaluate the overall goodness-of-fit of the clusters.⁴¹ A silhouette measure varies
21
22 between -1 and 1 based on the average distances between the objects. The value of a silhouette
23
24 measure less than 0.20 indicates a poor solution quality, a value between 0.20 and 0.50 suggests
25
26 a fair solution, whereas a value of more than 0.50 represents a good solution.⁴² Once categorized,
27
28 the clusters were then characterized based on various sociodemographic and clinical
29
30 characteristics. For the continuous variables, one-way ANOVA was used to determine the
31
32 psychosocial (health literacy and self-efficacy), clinical (e.g. number of medicines) and socio-
33
34 demographic (e.g. age) factors that varied between the clusters. For the categorical variables such
35
36 as gender and race, chi-square tests were used to examine the differences between the clusters.
37
38
39
40
41
42 SPSS version 23 was used for all the analyses.
43

44 *Patient and Public involvement*

45
46 No patients were involved in the study design, development of the research questions and
47
48 outcome measures, recruitment, or implementation. The results of the study will be disseminated
49
50 to study participants through access to the published article once published in the journal.
51
52

54
55
56
57
58
59
60

Results

One hundred and ninety-nine patients were approached and 174 patients participated (87.4% response rate). The participant's mean age was 58.74 (SD = 12.84). The majority were female (57.5%), non-Hispanic white (67.8%) and African American (24.7%). Approximately 62.1% had completed at least a college or technical degree, and 57.5% had an annual household income of equal or more than \$20,000. Of the 174 patients, 40.8% had low medication adherence, 35.1% had medium medication adherence, and 24.1% had high medication adherence.

The two-step cluster analysis produced four distinctive clusters categorized as ambivalent, skeptical, indifferent, and accepting. The characteristics of the clusters based on medication adherence, beliefs in medicines, illness perceptions, health literacy, self-efficacy, and all demographics are reported in Table 1. The distribution of participants across the clusters ranged from 17.2% to 30.5%. The silhouette measure was 0.4 which indicated a satisfactory cluster quality and the ratio of the largest to smallest cluster was acceptable at 1.77. As hypothesized, high concern beliefs was related to high threatening illness perceptions and low adherence and vice versa. Table 2 describes the distinctive psychosocial and clinical characteristics of each cluster. The ambivalent cluster (n = 30, 17.2%) included low adherent patients with high necessity beliefs, high concern beliefs, and high illness perceptions. The skeptical cluster (n = 53, 30.5%) included low adherent patients with low necessity beliefs, but high concern beliefs and high illness perceptions. Both the accepting (n = 40, 23.0%) and indifferent (n = 51, 29.3%) clusters were comprised of patients with high adherence. Significant differences were found between the ambivalent, skeptical, accepting and indifferent adherent clusters based on self-efficacy (p = 0.002), beliefs in medicines (p < 0.001), illness perception domains (consequence (p < 0.001), personal control (p < 0.001), treatment control (p < 0.001), identity (p < 0.001),

1
2
3 concern ($p < 0.001$), coherence ($p = 0.027$), and emotional representations ($p < 0.001$), and
4
5 hemoglobin A1c ($p < 0.05$) (Table 1). While non-adherent clusters had low self-efficacy and
6
7 high HbA1c levels, it was vice versa for the adherent clusters. Patients in the ambivalent non-
8
9 adherent cluster were younger in age compared to those in the adherent clusters, less likely to
10
11 have attended some college or technical school, and likely to be non-white.
12
13

14 **Discussion**

15
16 This study used the Extended Self-Regulatory Model to cluster the adherence behavior of
17
18 patients with type 2 diabetes based on beliefs in medicines and illness perceptions, as well as
19
20 examine the characteristics of the clusters and the significant differences between them. Four
21
22 clusters with distinct beliefs and psychosocial characteristics associated with each group were
23
24 formed. The adherence clusters developed in this study by using both beliefs in medicines and
25
26 illness perceptions are similar to the clusters formed by Horne et al in his previous studies where
27
28 only beliefs in medicines were used. By including illness perceptions and other psychosocial
29
30 correlates of adherence, this study identified other pertinent information related to each cluster
31
32 that may help in developing guided and targeted interventions for providers working with
33
34 diabetes patients who may be non-adherent.
35
36
37
38
39

40 Patients in the ambivalent cluster were the least adherent to their medicines followed by
41
42 the skeptical cluster. These clusters together comprised 48% of the whole sample. These results
43
44 are similar to previous studies where these specific clusters represent the non-adherent
45
46 proportion of a sample.^{21,24} Contrary to a prior study³⁹, ambivalent patients had the lowest
47
48 adherence to diabetes medicines, the strongest concerns about their medicines and the strongest
49
50 threatening illness perceptions. In spite of their strong concerns about medicines, ambivalent
51
52 patients also perceived that their medications were necessary to maintain their health. Further
53
54
55
56
57
58
59
60

1
2
3 analysis revealed that their strong threatening perceptions about diabetes were from their
4 individual illness perception domains including high emotional representations, lack of treatment
5 control, high concern about illness, less coherence, and experiencing many severe symptoms due
6 to diabetes. Despite the belief that medications are necessary, patients in the ambivalent cluster
7 may be cognitively and emotionally overwhelmed with the demands of managing diabetes.

Diabetes is psychologically demanding and requires adaptive self-care tasks related to being chronically ill, including taking medications as prescribed.⁴³⁻⁴⁵ Because of this, when patients fail to self-manage their disease, it may give rise to feelings of guilt, frustration, anger, and hopelessness. These negative feelings may foster a pessimistic attitude towards diabetes, leading to negative beliefs about the illness and medication, and poor medication adherence.⁴⁶

Ambivalent patients in this study also had the least self-confidence that they could take and manage their medications correctly and had the lowest health literacy scores. These patients also took the highest number of medicines, had the highest number of chronic illness, and had poor glycemic control (highest hemoglobin A1c values). In addition, ambivalent patients were the youngest among the four clusters and had the least education which might account for their inadequate health literacy and concerns about illnesses and medicines. Tailored adherence interventions aimed at these patients may need to build their self-efficacy and address their low health literacy. Prior research shows that by providing information in simple plain language, using teach-back techniques, and showing patients how they can be expert self-managers and engage in self-monitoring; patients are more likely to feel more in control of their illness, less concerned about the illness, and manage their illness more effectively.⁴⁷

In the skeptical cluster, patients had strong concerns about medicines and threatening illness perceptions, although not at a pronounced degree as the ambivalent group. They also did

1
2
3 not think their medications were necessary. Contrary to previous studies in asthma, epilepsy,
4 inflammatory bowel disease, depression and cardiac disease, where the skeptical groups were
5 most non-adherent to their medications^{24,39,40}, the skeptical group of patients with diabetes in
6 this study did not have the lowest medication adherence. Though this cluster of patients had
7 perceptions of strong consequences from the illness, lack of treatment control, high concerns,
8 high emotional representations, less understanding of their illness, were experiencing many
9 symptoms due to diabetes, and were not confident they could manage their medications; they
10 also had high health literacy. For these patients, it is possible that because they have an increased
11 ability to search, understand, and process health information; they are engaged in seeking
12 information to manage their diabetes themselves, perform other diabetes self-management
13 practices, and therefore do not believe they need medicines. A prior study has shown that
14 patients with no educational qualifications (possibly tied to health literacy) are likely to have
15 doubts about their personal need for medicines compared with patients with any formal
16 educational qualifications.⁴⁰ Additionally, their self-perceived better health status may also be
17 contributing to their perception that medications are not necessary for maintaining their health,
18 hence, making them skeptical. In spite of their high health literacy, skeptical patients' low self-
19 efficacy may lead to their poor glycemic control especially as prior studies report the strong
20 influence of self-efficacy on diabetes control.^{48,49} Adherence interventions that target concerns
21 about medicines and illness, but also aim to motivate patients towards medication use might need
22 to be developed for these group of patients.

49 Patients in the indifferent and accepting clusters were adherent to their medicines, though
50 different in their beliefs in medicines. Similar to prior studies^{21,24,39,40}, patients in the accepting
51 group were more likely to be adherent to their medicines. These patients are generally not
52
53
54
55
56
57
58
59
60

1
2
3 concerned about their illness, believe that their medications are necessary and are least concerned
4 about them, feel the most confident that they can take their medications correctly, and have the
5 ability to process and understand health information. This group of patients however still believe
6 that their diabetes affects their life, and still have some concern about it. The accepting patients
7 were the oldest in age, the most educated, and have had their diabetes longer compared to
8 patients in other clusters. Since these patients' HbA1c values still show that their diabetes is
9 uncontrolled and using medications as part of diabetes management may not be concerning;
10 interventions may seek to address concerns about their diabetes, especially as it relates to other
11 complex diabetes self-management issues such as checking blood sugars, exercising, and diet etc.
12 Since these older and well educated patients have had diabetes for a long time and use a lot of
13 medications, providers may continue to encourage self-monitoring of symptoms, adverse drug
14 events, and check for other indicators of poor diabetes outcomes such as high blood pressure and
15 high cholesterol.⁵⁰

32
33 Contrary to previous studies^{21,24} where patients who were in the indifferent cluster were
34 reported to be non-adherent to their medicines, the current study showed that the patients in this
35 cluster were adherent to their medicines and their diabetes seemed to be in better control than
36 patients in the three other clusters. Though the patients in the indifferent cluster were the least
37 likely to believe that their medications were necessary, they were also least concerned about their
38 medicines, were not threatened by their illness, and were not emotionally affected by it (low
39 emotional representation). Also, they experienced few symptoms due to their illness, and had the
40 least concern about their illness. It is also possible that because these patients were taking the
41 lowest number of medicines and had the lowest number of chronic illness, they were healthier
42 compared to other patients, and therefore more likely to easily manage their medicines. Providers

5
6

7
8 This study has several strengths. Horne et al (2009) classified patients' adherence
9 behaviors based on beliefs in medicines using the mid-point score of the Beliefs in Medicines
10 questionnaire. However, this current study used the clustering technique to allow for algorithm-
11 based grouping based on both beliefs in medicines and illness perceptions founded on the
12 Extended Self-Regulatory Model. Prior research has highlighted the importance of content and
13 theory-driven components to enable replication of successful adherence interventions.⁴⁷ While it
14 is important to address diabetes nonadherence via clinical interventions, we cannot underestimate
15 the impact of patient psychosocial factors such as their individual perceptions of medication and
16 illness, self-efficacy, and health literacy in the management of diabetes. Brief, valid, and reliable
17 questionnaires that can easily quantify these psychosocial factors are available and may be
18 included in adherence support programs.⁴⁰

33 The study limitations are the use of a convenience sample from two clinics in one state,
34 hereby limiting the generalizability of the study. The use of a self-reported measure to evaluate
35 medication adherence, rather than objective measures such as the use of pill counts might lead to
36 overestimation. However, prior studies show the reliability and validity of self-report adherence
37 measures. Data were collected either before or after patients' medical encounter depending on
38 the flow of the clinic. The timing of the medical encounter may influence patient responses to
39 questions about illness and treatment beliefs. This variable was not accounted for in the data
40 analysis. The concurrent assessment of illness perceptions, beliefs in medicines, and adherence
41 in a cross-sectional manner is a limitation. A longitudinal study that evaluates changes in beliefs
42 overtime and examines how these changes relate to changes in behavior and outcomes will be

3 considered in the future. HbA1c was measured retrospectively. Though we used the most recent
4 values from patients' medical record which is acceptable by clinical practitioners for standard
5 diabetes care, this retrospective measurement of HbA1c could have limited our results. Though the
6 B-IPQ total score categorizes respondents into two categories without taking into consideration
7 the individual domains of the illness perceptions, this was needed for clustering their adherence.

Once the clusters were formed, the illness perception domain characteristics of each cluster were analyzed and compared.

Conclusions

This study used a cluster analysis to characterize patients' adherence behavior based on their beliefs in both medicines and illnesses and psychosocial factors. Using evidence-based theoretical approaches, four clusters were formed with characteristics that suggest different types of interventions for each cluster. Medication nonadherence is a complex behavior to understand and targeted interventions are often recommended. Data that can help discriminate between large groups of non-adherent individuals is needed in developing more personalized interventions. Though a large number of patients in two separate clusters (ambivalent and skeptical) were non-adherent to their medicines; patients within each non-adherent clusters still had distinct beliefs in medicines, illness perceptions, and other psychosocial characteristics that may help providers target tailored behavioral, psychological-based adherence interventions (for ambivalent clusters), as well as education and motivation-based adherence interventions (for skeptical clusters). Also, patients who are adherent may still need interventions that support and/or enhance their use of medicines (for indifferent clusters), and support individualized self-management strategies used for control of illness (for accepting clusters).

Number of medications (Mean ± SD) ^{***}	7.77 ± 3.89	9.07 ± 4.21 ^g	8.19 ± 4.03 ^l	5.80 ± 2.86 ^{g, l, k}	8.75 ± 3.75 ^k
Number of illness (Mean ± SD) ^{**}	3.86 ± 1.82	4.50 ± 2.03 ^g	3.89 ± 1.96	3.22 ± 1.47 ^{g, k}	4.28 ± 1.66 ^k
Duration of diabetes diagnosed (Mean ± SD) [*]	9.58 ± 7.08	8.75 ± 5.79	9.25 ± 6.30	8.03 ± 7.14 ^k	12.61 ± 8.13 ^k
HbA1c level [*]	7.66 ± 1.64	8.31 ± 2.14 ^g	7.86 ± 1.58	7.17 ± 1.32 ^g	7.52 ± 1.51
Health status ^{e, **}	2.64 ± 0.80	2.13 ± 0.90 ^{f, g}	2.72 ± 0.77 ^f	2.86 ± 0.75 ^g	2.65 ± 0.70

^a Self-reported medication adherence was measured with the 8-item Morisky Medication Adherence Scale.

^b Higher scores indicate higher specific illness perceptions. Personal control, treatment control, and coherence are reverse scored.

^c The score of the self-efficacy on medication use ranges from 13 to 39. 13 items on a 3 point scale. Higher scores indicate higher levels of self-efficacy.

^d Health literacy was measured with the Newest Vital Sign (NVS).

^e One item on a 5 point scale. Higher scores indicate better self-reported health status.

^{f-k} Significant differences based on the post-hoc analysis.

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Table 2 Beliefs, psychosocial and clinical characteristics of the clusters

	Clusters with non-adherence behavior		Clusters with adherence behavior	
	Cluster 1 (Ambivalent)	Cluster 2 (Skeptical)	Cluster 3 (Indifferent)	Cluster 4 (Accepting)
Medication Adherence	Low adherence	Low adherence	High adherence	High adherence
Beliefs in medicines	High NB	Low NB	Low NB	High NB
	High CB	High CB	Low CB	Low CB
Illness perceptions	High IP	High IP	Low IP	Low IP
Self-efficacy	Low SE	Low SE	High SE	High SE
Health literacy	Low HL	High HL	High HL	High HL
Glycemic control	High HbA1c	High HbA1c	Low HbA1c	Low HbA1c
Illness perception domains	High Consequence	High Consequence	Low consequence	High consequence
	High treatment control	High treatment control	Low treatment control	Low treatment control
	High identity	High identity	Low identity	Low identity
	High concern	High concern	Low concern	High concern
	High coherence	High coherence	Low coherence	Low coherence

High emotional representation	High emotional representation	Low emotional representation	Low emotional representation
----------------------------------	----------------------------------	---------------------------------	---------------------------------

The high and low values for each variable is compared based on the mean values from all participants.

CB: concern beliefs; HbA1c: hemoglobin A1c levels; HL: health literacy; IP: illness perceptions; NB: necessity beliefs; SE: self-efficacy.

MMAS-8 Retroactive & Corrective License

This Agreement entered into on January , 2018 between the the University of Wisconsin-Madison School of Pharmacy, 777 Highland Ave., Madison, WI 53705 ("Licensee"); MMAS Research, LLC (MMAS) 14725 NE 20th St. Bellevue Washington 98007 USA ("Licensor") shall constitute a retroactive and corrective license to use the MORISKY Medication Adherence Scale (MMAS-8) from March 2016- August 2016 to assess patients in the association of health literacy and self-efficacy on medication adherence and diabetes control study.

SECTION 1. TERMS OF USAGE

Ownership and Fees: All psychometric products as well as their certified translations, adaptations, computer programs, software and scoring and coding algorithms, trade secrets, and any other related documents and information (including those in electronic form) which embody or are related to the Morisky Widget or MMAS tools (including without limitation the Morisky Medication Adherence Scale 4- and 8-item versions, Morisky Medication Adherence Protocol and any documentation thereof are the intellectual property of Licensor.

Translations: Permission will only be granted to use MMAS certified translations from the Morisky Widget or with special arrangements approved and signed by the Licensor. There are no exceptions.

Changes or any modifications to the wording, phrasing or scoring of the MMAS-8 require written permission. If any changes made to the wording, phrasing or scoring of any MMAS item or other Morisky document without permission, it will be considered a breach of the Morisky Widget license and the Licensor will have the right to suspend or terminate this Agreement.

Coding and scoring criteria of the MMAS are trade secrets of Licensor and as such can NEVER be divulged in any publication, presentation, or website without prior written permission from Licensor. If Licensee divulges MMAS scoring and coding criteria it will be considered a breach of the MMAS-8 license and the Licensor will have the right to suspend or terminate this Agreement.

Copyright: Permission to use the trademarks Morisky Widget, Morisky Medication Adherence Scale, "MMAS" is not and will not be granted for any unauthorized use or translations of the MMAS or other Licensor or Morisky intellectual property, in whole or in part. No electronic questionnaires, analyses, research results or publications based on unauthorized use of the MMAS will be permitted. The MMAS SCALE legend and required citations provided in Appendix 1 must be included in all manuscripts, web postings or other publication containing MMAS descriptions or results

In case of scientific, administrative or intellectual property misconduct in using the MORISKY system of questionnaires or the Morisky name or MMAS names, Licensor reserves the right to withdraw permission for use and to pursue all legal remedies. The Courts of the State of California and the U.S. District Court shall have personal and subject matter jurisdiction over any lawsuit relating to this Agreement. Venue shall be Los Angeles. This Agreement will be governed by the laws of California, as well as federal intellectual property laws. In the event of any litigation, the prevailing party, in addition to any other relief, shall be entitled to recover its reasonable attorney fees incurred.

The Morisky Widget, MMAS scales, scoring, coding agreed to in this license are non-transferrable and cannot be used by anyone other than the Licensee.

All licensees must submit to MMAS Research LLC all presentations and manuscripts that are being

1
2 considered for abstracts/poster presentations or publication to make certain that all copyright and
3 trademark requirements are included in all manuscripts submitted for publication. This is to protect
4 the Licensee as MMAS Research LLC has encountered many violations of federal and international
5 copyright laws from clients as well as individuals who use MMAS intellectual property without
6 following the required copyright and trademark guidelines.
7
8

9 **SECTION 2. FEES**

10
11 In consideration of Licensor granting Licensee a retroactive and corrective MMAS license. Licensee
12 agrees to pay Licensor a onetime licensee fee of \$3500.00 (USD) within ten (10) days of execution of this
13 Agreement by the parties. A 10% late fee will be assessed to all fees thirty (30) days or more past due.
14 The fee includes corrective measures required by Licensor to cure Licensee's unauthorized use and
15 modification of the MMAS-8.
16
17

18 **SECTION 3. DUTIES OF THE LICENSEE**

19
20 Licensee agrees to adhere to all the terms and requirements of the MMAS-8 retroactive and
21 corrective license, and the copyright guidelines in Appendix 1.
22
23

24 Licensee agrees to perform all of the corrective measures required by the Licensor to obtain a
25 MMAS-8 retroactive and corrective license.
26
27

28
29 Licensee agrees to correct the use of an incorrect MMAS-8 scoring and coding criteria that was
30 used for 174 MMAS tests in the association of health literacy and self-efficacy on medication
31 adherence and diabetes control study.
32

33 Licensee will submit to the Licensor in a CSV file template, the patient's response to the MMAS-8
34 questionnaire to correct the scoring and coding of 174 MMAS-8 patient tests.
35
36

37 Licensee agrees to certify the destruction of all MMAS-8 scales in its possession, both MMAS-8
38 paper questionnaires and MMAS-8 electronic questionnaires.
39
40

41 **SECTION 4 DUTIES OF LICENSOR**

42
43 Licensor will provide Licenss guidance and support for Licensee to implement the corrective measures
44 necessary to cure its misuse of the MMAS-8.
45
46

47 If Licensee adheres to the terms and condition of this Morisky Widget license,
48

49 Licensor waives all prior claims arising out of Licensee's misuse of the MMAS-8, all such misuse been
50 now cured and the claims resolved and settled and that Licensor as the copyright and trademark holder,
51 will agree not to sue or take any action against Licensee because of their past improper use of the
52 MMAS-8

44
45

46 Keywords: Medication Adherence, Beliefs in Medicines, Illness Perceptions, Type 2 diabetes,
47 Clustering
48
49

1
2
3 **Objectives:** To cluster the adherence behaviors of patients with type 2 diabetes based on their
4 beliefs in medicines and illness perceptions and examine the psychosocial, clinical, and
5 sociodemographic characteristics of patient clusters.
6
7

8
9
10 **Design:** Cross-sectional study
11

12 **Setting:** A face-to-face survey was administered to patients at two family medicine clinics in the
13 Midwest, USA.
14

15 **Participants:** One hundred and seventy four English-speaking ≥ 20 years old adult patients with
16 type 2 diabetes who were prescribed at least one oral diabetes medicine daily were recruited
17 using convenience sampling.
18
19

20 **Primary and secondary outcome measures:** Beliefs in medicines and illness perceptions were
21 assessed using the Beliefs about Medicines Questionnaire and the Brief Illness Perception
22 Questionnaire respectively. Self-reported medication adherence was assessed using the Morisky
23 Medication Adherence Scale. Psychosocial correlates of adherence, health literacy and self-
24 efficacy, were measured using the Newest Vital Sign and the Self-efficacy for Appropriate
25 Medication Use respectively. Two-step cluster analysis was used to classify patients.
26
27

28 **Results:** Participants' mean age was 58.74 (SD = 12.84). The majority were female (57.5%).
29 Four clusters were formed (non-adherent clusters: ambivalent and skeptical; adherent clusters;
30 indifferent and accepting). The ambivalent cluster (n = 30, 17.2%) included low adherent
31 patients with high necessity beliefs, high concern beliefs, and high illness perceptions. The
32 skeptical cluster (n = 53, 30.5%) included low adherent patients with low necessity beliefs, but
33 high concern beliefs and high illness perceptions. Both the accepting (n = 40, 23.0%) and
34 indifferent (n = 51, 29.3%) clusters were comprised of patients with high adherence. Significant
35 differences between the ambivalent, skeptical, accepting, and indifferent adherent clusters were
36
37

59
60

1
2
3 based on self-efficacy, illness perception domains (treatment control, coherence), and
4
5 hemoglobin A1c ($p < 0.01$).
6

7 **Conclusions:** Patients with diabetes in specific non-adherent and adherent clusters still have
8
9 distinct beliefs as well as psychosocial characteristics that may help providers target tailored
10
11 medication adherence interventions.
12
13

14 15 16 **Strengths and limitations of this study**

- 17 • This is the first study to use a clustering technique to allow for algorithm-based grouping
18
19 based on both beliefs in medicines and illness perceptions founded on the Extended Self-
20
21 Regulatory Model among patients with diabetes.
22
23
- 24 • This study highlighted the importance of content and theory-driven components to enable
25
26 a possible mechanism for the development of tailored adherence interventions.
27
28
- 29 • This study focused on the impact of patient psychosocial factors such as their individual
30
31 perceptions of medication and illness, self-efficacy, and health literacy in the
32
33 management of diabetes.
34
35
- 36 • A convenience sample from two clinics in one state, hereby limiting the generalizability
37
38 of the study.
39
40
- 41 • The use of a self-reported measure to evaluate medication adherence, rather than
42
43 objective measures.
44
45
46
47
48

49 **Funding statement:** This research received no specific grant from any funding agency in the
50
51 public, commercial or not-for-profit sectors.
52

53 **Competing Interests:** The authors have no competing interests.
54
55
56
57
58
59

1
2
3 **Author Contributors:** OOS and EU designed the study. OOS, YH, and CL were involved in
4 data collection and data analysis. OOS wrote the manuscript, and EU and YH critically revised
5 the content. All authors approved the final version of the manuscript.
6
7

8
9

Introduction

Medication adherence, defined as the extent to which taking medications corresponds with recommendations by a healthcare provider is essential for treatment success.¹ Poor adherence results in increased risk of mortality, increased emergency room visits, and reduced quality of life.²⁻⁵ In general, rates of medication adherence are below 50%.⁶ However, for patients with type 2 diabetes, these rates are as low as 36%.⁷ It is estimated that a 10% improvement in diabetes medication adherence would lead to at least a 6.6% reduction in hospitalizations.⁷

Among patients with diabetes, medication adherence has been found to be influenced by psychosocial factors, such as beliefs about illness and treatment, self-efficacy and perceived control, self-regulation, and emotional states.⁸ Of the various factors that influence medication adherence, Horne and Weinman (2002) showed that sociodemographic and clinical factors explain only a small amount of variance in medication adherence, whereas illness perceptions and patient beliefs in medicines are substantial independent predictors.⁹ Since patient clinical and sociodemographics are difficult to change, it makes sense to focus on patient factors that are modifiable, practical for interventions, and can be addressed by health providers.

Studies based on the Extended Self-Regulatory Model show that when patients are diagnosed with an illness, they develop a pattern of beliefs about their condition and treatment, which then influences their medication adherence.¹⁰⁻¹⁵ The Self-Regulatory Model (also called the Common Sense Model) was developed to explain illness-related coping behaviors including adherence to treatment, based on patient perceptions of their illness.¹⁶ Horne et al. extended the Self-Regulatory Model by integrating beliefs about treatment when research identified beliefs about treatment as proximal determinants of coping strategies such as medication adherence compared with illness perceptions.^{9,10} In prior research, Phillips and colleagues suggested that

1
2
3 patient adherence was greater when illness and treatment perceptions were addressed or
4
5 discussed during patients' medical encounter, and that healthcare providers were better able to
6
7 judge patient agreement regarding the illness and treatment when patients reported these
8
9 discussions occurred.^{17,18}

12 To design feasible and useful medication adherence interventions, Horne et al. originally
13
14 classified patients with chronic illnesses into four attitudinal groups (accepting, ambivalent,
15
16 skeptical, and indifferent) based on their beliefs about their treatment.¹⁹ While “accepting”
17
18 patients, with high necessity beliefs and low concerns, had the highest medication adherence,
19
20 “skeptical” patients, with low perceived need of medications and high concerns, had the lowest
21
22 adherence levels. The other patient groups, including the “ambivalent” (high necessity beliefs
23
24 and high concerns), and the “indifferent” (low necessity beliefs and low concerns) were also
25
26 likely to be non-adherent.¹⁹ Though medication non-adherence is a common problem among
27
28 patients with chronic illnesses, they hardly discuss this behavior with their health providers
29
30 during routine visits.²⁰ Various available tools used to identify medication adherence are not
31
32 usable in clinical consultations because of the short time available to providers.²¹ Hence,
33
34 clustering patients' adherence behavior based on their beliefs may provide a mechanism for
35
36 providers to focus on the specific belief needs of the patients in the context of their psychosocial
37
38 characteristics. A previous study based on the Extended Self-Regulatory Model used both illness
39
40 perceptions and beliefs in medicines to cluster patients with asthma and was able to develop the
41
42 same clusters as developed by Horne et al.²² Additionally, each cluster had psychosocial
43
44 characteristics that were unique to them. However, further studies were needed to determine
45
46 whether the four attitudinal group structure that includes illness perceptions also holds with other
47
48 chronic disease conditions.
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 Clustering will provide a mechanism for providers to have a more tailored approach to
4 addressing adherence than the general ‘one size fits all’ approach. For example, the counseling
5 needed for a skeptical patient can be very different from an ambivalent patient. Though both
6 these sets of patients have issues with their beliefs in medicines, they are quite different in their
7 beliefs and psychosocial characteristics. Clustering can be done during the visit with the provider.
8
9 A short validated questionnaire or online profiling tool that patients complete in advance of a
10 consultation could be developed, which automatically calculates which cluster a patient belongs
11 to. The patient’s cluster with its unique characteristics can be included in a patient’s record, and
12 available to providers during the patient visit, similar to reviewing a patient’s medical history.
13
14 This will allow for an effective tailored counseling approach during the short visit time.

15
16
17
18
19
20
21
22
23
24
25
26 Diabetes is a chronic disease condition with reportedly high non-adherence rates.^{23,24}
27
28 Thus, developing a mechanism that will assist physicians in providing tailored communications
29 to patients who are non-adherent with their diabetes medications can be effective and beneficial.
30
31

32
33 The objectives of this study were to:

- 34
35 1) Cluster the adherence behaviors of patients with type 2 diabetes based on their beliefs in
36 medicines and illness perceptions.
37
38 2) Examine the psychosocial, clinical and sociodemographic characteristics of patient clusters.
39
40
41

42 This study hypothesized that patient clusters with high concern beliefs and low necessity
43 beliefs will also have high threatening illness perceptions, and groups with low concern beliefs
44 and high necessity beliefs will have low threatening illness perceptions. It is also hypothesized
45 that identified patient clusters will have unique psychosocial, clinical, and sociodemographic
46 characteristics.

2
3 Using a cross-sectional study design, a face-to-face survey was administered to English-speaking,
4 ≥ 20 years old patients, with type 2 diabetes who were prescribed at least one oral diabetes
5
6 medicine daily. Patients were recruited using convenience sampling. Information on eligible
7
8 patients was retrieved from the electronic health record database of two family medicine clinics
9
10 in a Midwestern state in the United States.
11
12
13

14 *Data collection*

15
16 Front desk receptionist at two clinics provided study information sheets to eligible patients who
17
18 were waiting for their appointment. After patients reviewed the information, they met with a
19
20 research assistant to indicate their interests in participating. The research assistant verified the
21
22 patient's eligibility from the clinic's patient log, administered the informed consent form, and
23
24 completed the 10-to-20-minute survey with the consented participant in a private area at the
25
26 clinic. Participants were allowed to complete the survey before or after their scheduled clinic
27
28 appointments, depending on clinic flow and their preferences. Informed consent was obtained
29
30 from all individual participants included in the study. All data collection occurred from March
31
32 2016 to August 2016. Participants were compensated with US\$25 cash, upon completion of the
33
34 survey. The University Health Sciences Institutional Review Board approved the study.
35
36
37
38
39

40 *Measures*

41
42 Self-reported medication adherence was assessed using the 8-item Morisky Medication
43
44 Adherence Scale (MMAS-8), a widely used scale in patients with diabetes.²⁵⁻²⁹ The total score of
45
46 the MMAS-8 ranged from 0 to 8, and MMAS-8 scores of < 6 , 6 to < 8 , and 8 reflected low,
47
48 medium, and high medication adherence, respectively.²⁵ The 10-item Beliefs in Medicines
49
50 Questionnaire (BMQ) was used to measure patient beliefs in medications.³⁰ The BMQ includes
51
52 the necessity beliefs and concern beliefs sub-scales measured on five-point Likert-type scales
53
54
55
56
57
58
59
60

1
2
3 with 'strongly disagree' to 'strongly agree' response options. The range of scores for each sub-
4 scale was 5-25, with a higher score meaning stronger concern beliefs or stronger necessity
5 beliefs about the medicine.³⁰ The 8-item Brief-Illness Perception Questionnaire (B-IPQ) was
6
7 used to measure patients' perceptions about diabetes.³¹ This validated instrument includes survey
8 items assessing patient illness perceptions about diabetes along the cognitive domains of the self-
9 regulatory model as well as their emotional responses to having diabetes. Each survey item of the
10 B-IPQ was assessed on a scale of 0-10 with higher scores indicating stronger threatening
11 perceptions along the illness perception dimensions.³¹
12
13
14
15
16
17
18
19
20

21 Finally, we assessed other patient psychosocial correlates of medication adherence, i.e.
22 health literacy and self-efficacy. Health literacy assessed using the 6-item Newest Vital Sign
23 (NVS) has been extensively used across studies including patients with type 2 diabetes and can
24 be completed in a short time (3-5 minutes).³²⁻³⁵ Each question was scored as "0" for an incorrect
25 response and "1" for a correct response for a total score of 0 to 6. Patients with scores less than 2
26 represented a high likelihood of inadequate health literacy, 2 to 3 indicated the possibility of
27 marginal health literacy, and more than 3 suggested adequate health literacy.^{32,36}
28
29
30
31
32
33
34
35
36

37 Self-efficacy measured using the 13-item Self-efficacy for Appropriate Medication Use
38 Scale (SEAMS) was used in examining medication self-efficacy in chronic disease management,
39 and is appropriate regardless of patient literacy skills.^{37,38} Patients indicated under a range of
40 situations, their level of confidence regarding taking medications correctly using a 3-point Likert
41 scale (1 = not confident, 2 = somewhat confident, and 3 = very confident). The total score of the
42 SEAMS ranged from 13 to 39 with higher scores indicating more confidence in adhering to
43 medication use.³⁷

60

1
2
3 Other variables included sociodemographic factors, such as age, gender, highest
4 education level, race, health insurance, and the annual household income level; patient clinical
5 factors, such as the number of chronic illnesses, self-reported health status, number of
6 medications used, frequency of daily diabetes medication use, duration of diagnosis of type 2
7 diabetes, and whether the patient used insulin or not. Besides the main predictor variables,
8 patients' hemoglobin A1c (HbA1c) values in the prior six months were retrieved from electronic
9 medical records, with lower HbA1c values $\leq 7.0\%$ representing better glycemic control.³⁹ The
10 average duration between the day of the latest HbA1c testing and the day of the patient
11 completing the survey was 43.3 ± 84.6 days (median: 7 days).

22

23 *Data analysis*

24
25
26 A two-step cluster analysis was used to classify patients' medication adherence behavior based
27 on their beliefs in medicines and illness perceptions.⁴⁰ The number of clusters to be formed was
28 kept a priori at four, a number determined by the researchers based on Horne's earlier studies
29 and our prior work.^{19,21,22,41,42} The cluster analysis technique organizes observed data (e.g.
30 patients) into meaningful groups or clusters based on combinations of the independent variables
31 (e.g. beliefs in medicines and illness perceptions). This process maximizes the similarity of cases
32 within each cluster, but also maximizes the dissimilarity between the groups based on the log-
33 likelihood distance between the data points.⁴⁰ Using this method allows the clusters to be created
34 without a preconceived notion of what the clusters may look like. Though there are no rules-of-
35 thumb about the sample size necessary for cluster analysis, prior researchers suggested that the
36 adequate sample size for cluster analysis should be at least 2^m cases, preferably 5×2^m cases,
37 where m is the number of clustering variables.^{40,43} Since we used 3 variables (i.e. concern beliefs,
38 necessity beliefs, and illness perceptions) for the clustering analysis, a minimal sample size to

1
2
3 include no less than 8 cases, preferably more than 40 cases, is sufficient to perform a cluster
4 analysis. Additionally, based on an analysis of cluster studies, Dolnicar reports that the median
5 sample size is 293.⁴⁴ In the first step, each data record was either considered as a new cluster or
6 was added to a previously formed cluster. In the second step, the clusters formed from the first
7 step were compared and merged based on the distance between them. Then, we assessed the
8 goodness of fit of the clustering solution. The silhouette measure of cohesion and separation was
9 used to evaluate the overall goodness-of-fit of the clusters.⁴⁵ A silhouette measure varies between
10 -1 and 1 based on the average distances between the objects. The value of a silhouette measure
11 less than 0.20 indicates a poor solution quality, a value between 0.20 and 0.50 suggests a fair
12 solution, whereas a value of more than 0.50 represents a good solution.⁴⁶ Once categorized, the
13 clusters were then characterized based on various sociodemographic and clinical characteristics.
14 For the continuous variables, one-way ANOVA was used to determine the psychosocial (e.g.
15 health literacy and self-efficacy), clinical (e.g. number of medicines) and sociodemographic (e.g.
16 age) factors that varied between the clusters. For the categorical variables such as gender and
17 race, chi-square tests were used to examine the differences between the clusters. SPSS (IBM
18 Corp. Released 2015. IBM SPSS Statistics for Windows, Version 23.0. Armonk, NY: IBM Corp.)
19 was used for all the analyses.

20 21 22 *Patient and Public involvement*

23 No patients were involved in the development of the study design, the research questions, and
24 outcome measures. The results of the study will be disseminated to study participants through
25 access to the published article once published in the journal.

26 27 28 **Results**

1
2
3 One hundred and ninety-nine patients were approached and 174 patients participated (87.4%
4 response rate). The participant's mean age was 58.74 (SD = 12.84). The majority were female
5 (57.5%), non-Hispanic white (67.8%) and African American (24.7%). Approximately 62.1% had
6 completed at least a college or technical degree, and 57.5% had an annual household income of
7 equal or more than \$20,000. Of the 174 patients, 40.8% had low medication adherence, 35.1%
8 had medium medication adherence, and 24.1% had high medication adherence.
9
10
11
12
13
14
15

16
17 The two-step cluster analysis produced four distinctive clusters categorized as ambivalent,
18 skeptical, indifferent, and accepting. The characteristics of the clusters based on medication
19 adherence, beliefs in medicines, illness perceptions, health literacy, self-efficacy, and all
20 demographics are reported in Table 1. The distribution of participants across the clusters ranged
21 from 17.2% to 30.5%. The silhouette measure was 0.4, which indicated a satisfactory cluster
22 quality and the ratio of the largest to smallest cluster was acceptable at 1.77 (Figure 1). As
23 hypothesized, high concern beliefs were related to high threatening illness perceptions and low
24 adherence and vice versa. Table 2 describes the distinctive psychosocial and clinical
25 characteristics of each cluster. The ambivalent cluster (n = 30, 17.2%) included low adherent
26 patients with high necessity beliefs, high concern beliefs, and high illness perceptions. The
27 skeptical cluster (n = 53, 30.5%) included low adherent patients with low necessity beliefs, but
28 high concern beliefs and high illness perceptions. Both the accepting (n = 40, 23.0%) and
29 indifferent (n = 51, 29.3%) clusters were comprised of patients with high adherence. Significant
30 differences were found between the ambivalent, skeptical, accepting, and indifferent adherent
31 clusters based on self-efficacy (p = 0.002), beliefs in medicines (p < 0.001), illness perception
32 domains [consequence (p < 0.001), personal control (p < 0.001), treatment control (p < 0.001),
33 identity (p < 0.001), concern (p < 0.001), coherence (p = 0.027), and emotional representations

3 (p < 0.001)], and HbA1c (p < 0.05) (Table 1). While non-adherent clusters had low self-efficacy
4 and high HbA1c levels, it was vice versa for the adherent clusters. Patients in the ambivalent
5 non-adherent cluster were younger in age compared to those in the adherent clusters, less likely
6 to have attended some college or technical school, and likely to be non-white.

11 **Discussion**

12
13
14 This study used the Extended Self-Regulatory Model to cluster the adherence behavior of
15 patients with type 2 diabetes based on beliefs in medicines and illness perceptions, as well as
16 examine the characteristics of the clusters, and the significant differences between them. Four
17 clusters with distinct beliefs and psychosocial characteristics associated with each group were
18 formed. The adherence clusters developed in this study by using both beliefs in medicines and
19 illness perceptions are similar to the clusters formed by Horne et al. in his previous studies where
20 only beliefs in medicines were used.^{19,47} By including illness perceptions and other psychosocial
21 correlates of adherence, this study identified other pertinent information related to each cluster
22 that may help in developing guided and targeted interventions for providers working with
23 patients with diabetes who may be non-adherent.

29
30
31
32
33
34
35
36

37
38 Patients in the ambivalent cluster were the least adherent to their medicines followed by
39 the skeptical cluster. These clusters together comprised 48% of the whole sample. These results
40 are similar to previous studies where these specific clusters represent the non-adherent
41 proportion of a sample.^{19,22} Contrary to a prior study, ambivalent patients had the lowest
42 adherence to diabetes medicines, the strongest concerns about their medicines and the strongest
43 threatening illness perceptions.⁴¹ In spite of their strong concerns about medicines, ambivalent
44 patients also perceived that their medications were necessary to maintain their health. Further
45 analysis revealed that their strong threatening perceptions about diabetes were from their

1
2
3 individual illness perception domains including high emotional representations, lack of treatment
4 control, high concern about illness, and less coherence. Despite the belief that medications are
5 necessary, patients in the ambivalent cluster may be cognitively and emotionally overwhelmed
6
7 by the demands of managing diabetes. Diabetes is psychologically demanding and requires
8
9 adaptive self-care tasks related to being chronically ill, including taking medications as
10
11 prescribed.⁴⁸⁻⁵⁰ Because of this, when patients fail to self-manage their disease, it may give rise
12
13 to feelings of guilt, frustration, anger, and hopelessness. These negative feelings may foster a
14
15 pessimistic attitude towards diabetes, leading to negative beliefs about the illness and medication,
16
17 and poor medication adherence.⁵¹

Ambivalent patients in this study also had the least self-confidence that they could take
and manage their medications correctly, and had the lowest health literacy scores. These patients
also took the highest number of medicines, had the highest number of chronic illness, and had
poor glycemic control (highest HbA1c values). In addition, ambivalent patients were the
youngest among the four clusters and had the least education, which might account for their
inadequate health literacy and concerns about illnesses and medicines. Tailored adherence
interventions aimed at these patients may need to build their self-efficacy and address their low
health literacy. Prior research shows that by providing information in simple plain language,
using teach-back techniques, and showing patients how they can be expert self-managers and
engage in self-monitoring; patients are more likely to feel more in control of their illness, less
concerned about the illness, and manage their illness more effectively.⁵²

In the skeptical cluster, patients had strong concerns about medicines and threatening
illness perceptions, although not at a pronounced degree as the ambivalent group. They also did
not think their medications were necessary. Contrary to previous studies in asthma, epilepsy,

1
2
3 inflammatory bowel disease, depression, and cardiac disease, where the skeptical groups were
4 most non-adherent to their medications, the skeptical group of patients with diabetes in this study
5 did not have the lowest medication adherence.^{21,22,41} Though this cluster of patients had
6 perceptions of strong consequences from the illness, lack of treatment control, high concerns and
7 emotional representations, were experiencing many symptoms due to diabetes, and were not
8 confident they could manage their medications; they also had high health literacy and good
9 understanding of their diabetes. For these patients, it is possible that because they have an
10 increased ability to search, understand, and process health information; they are engaged in
11 seeking information to manage their diabetes themselves, perform other diabetes self-
12 management practices, and therefore do not believe they need medicines. A prior study has
13 shown that patients with no educational qualifications (possibly tied to health literacy) are likely
14 to have doubts about their personal need for medicines compared with patients with any formal
15 educational qualifications.²¹ Additionally, their self-perceived better health status may also be
16 contributing to their perception that medications are not necessary for maintaining their health,
17 hence, making them skeptical. In spite of their high health literacy, skeptical patients' low self-
18 efficacy may lead to their poor glycemic control especially as prior studies report the strong
19 influence of self-efficacy on diabetes control.^{53,54} Adherence interventions that target concerns
20 about medicines and illness, but also aim to motivate patients towards medication use might need
21 to be developed for these group of patients.

43
44
45
46
47 Patients in the indifferent and accepting clusters were adherent to their medicines, though
48 different in their beliefs in medicines. Similar to prior studies, patients in the accepting group
49 were more likely to be adherent to their medicines.^{19,21,22,41} These patients are generally not
50 concerned about their illness, believe that their medications are necessary and are least concerned
51
52
53
54
55
56
57
58
59
60

1
2
3 about them, feel the most confident that they can take their medications correctly, and have the
4 ability to process and understand health information. This group of patients, however, still
5
6 believe that their diabetes affects their life, and still have some concern about it. The accepting
7
8 patients were the oldest in age, the most educated, and have had their diabetes longer compared
9
10 to patients in other clusters. Since these patients' HbA1c values still show that their diabetes is
11
12 uncontrolled and using medications as part of diabetes management may not be concerning;
13
14 interventions may seek to address concerns about their diabetes, especially as it relates to other
15
16 complex diabetes self-management issues, such as checking blood sugars, exercising, and diet,
17
18 etc. Since these older and well-educated patients have had diabetes for a long time and used
19
20 many medications, providers may continue to encourage self-monitoring of symptoms, adverse
21
22 drug events, and check for other indicators of poor diabetes outcomes, such as high blood
23
24 pressure and high cholesterol.⁵⁵
25
26
27
28
29

30
31 Contrary to previous studies where patients who were in the indifferent cluster were
32
33 reported to be non-adherent to their medicines, the current study showed that the patients in this
34
35 cluster were adherent to their medicines and their diabetes seemed to be in better control than
36
37 patients in the three other clusters.^{19,22} Though the patients in the indifferent cluster were the
38
39 least likely to believe that their medications were necessary, they were also least concerned about
40
41 their medicines, were not threatened by their illness, and were not emotionally affected by it (low
42
43 emotional representation). Also, they experienced few symptoms and had the least concern about
44
45 their illness. It is also possible that because these patients were taking the lowest number of
46
47 medicines and had the lowest number of chronic illness, they were healthier compared to other
48
49 patients, and therefore more likely to easily manage their medicines. Providers may continue to
50
51
52
53
54
55
56
57
58
59
60

1
2
3 address the needs for taking medicines and provide interventions that emphasize the need for
4
5 taking medicines.
6

7
8 This study has several strengths. Horne et al. (2009) classified patients' adherence
9
10 behaviors based on beliefs in medicines using the mid-point score of the Beliefs in Medicines
11
12 questionnaire.¹⁹ However, this current study used the clustering technique to allow for algorithm-
13
14 based grouping based on both beliefs in medicines and illness perceptions founded on the
15
16 Extended Self-Regulatory Model. Prior research has highlighted the importance of content and
17
18 theory-driven components to enable replication of successful adherence interventions.⁵² While it
19
20 is important to address diabetes nonadherence via clinical interventions, we cannot underestimate
21
22 the impact of patient psychosocial factors such as their individual perceptions of medication and
23
24 illness, self-efficacy, and health literacy in the management of diabetes. Brief, valid, and reliable
25
26 questionnaires that can easily quantify these psychosocial factors are available and may be
27
28 included in adherence support programs.²¹
29
30
31
32

33 The study limitations are the use of a convenience sample from two clinics in one state,
34
35 hereby limiting the generalizability of the study. The use of a self-reported measure to evaluate
36
37 medication adherence, rather than objective measures such as the use of pill counts might lead to
38
39 overestimation. However, prior studies show the reliability and validity of self-report adherence
40
41 measures.^{25,27} Data were collected either before or after patients' medical encounter depending
42
43 on the flow of the clinic. The timing of the medical encounter may influence patient responses to
44
45 questions about illness and treatment beliefs. This variable was not accounted for in the data
46
47 analysis. The concurrent assessment of illness perceptions, beliefs in medicines, and adherence
48
49 in a cross-sectional manner is a limitation. A longitudinal study that evaluates changes in beliefs
50
51 over time and examines how these changes relate to changes in behavior and outcomes will be
52
53
54
55
56
57
58
59
60

1
2
3 considered in the future. Hemoglobin A1c was measured retrospectively. Though we used the
4 most recent values from patients' medical record which is acceptable by clinical practitioners for
5 standard diabetes care, this retrospective measurement of HbA1c could have limited our results.
6
7
8
9
10 Though the B-IPQ total score categorizes respondents into two categories without taking into
11 consideration the individual domains of the illness perceptions, this was needed for clustering
12 their adherence. Once the clusters were formed, the illness perception domain characteristics of
13
14
15
16
17 each cluster were analyzed and compared.

18 19 **Conclusions**

20
21 This study used a cluster analysis to characterize patients' adherence behavior based on their
22 beliefs in both medicines and illnesses and psychosocial factors. Using evidence-based
23
24
25
26 theoretical approaches, four clusters were formed with characteristics that suggest different types
27 of interventions for each cluster. Medication nonadherence is a complex behavior to understand,
28 and targeted interventions are often recommended. Data that can help discriminate between large
29
30
31
32 groups of non-adherent individuals is needed in developing more personalized interventions.

Table 1 Mean score and percentage comparison of adherence, psychosocial factors, and demographics between clusters (n=174)

Variables	Total	Cluster 1 (Ambivalent)	Cluster 2 (Skeptical)	Cluster 3 (Indifferent)	Cluster 4 (Accepting)
Number of subjects	174	30 (17.2%)	53 (30.5%)	51 (29.3%)	40 (23.0%)
Medication adherence ^{a, ***}	5.87 ± 1.87	4.87 ± 1.78 ^{g, h}	5.43 ± 1.89 ^j	6.39 ± 1.67 ^g	6.53 ± 1.72 ^{h, j}
Necessity beliefs (Mean ± SD) ^{***}	18.88 ± 4.27	21.93 ± 2.77 ^{f, g}	18.23 ± 1.76 ^{f, i, j}	14.59 ± 3.71 ^{g, i}	22.93 ± 2.18 ^j
Concern beliefs (Mean ± SD) ^{***}	13.24 ± 4.35	18.83 ± 3.66 ^{f, g, h}	14.85 ± 2.07 ^{f, i, j}	11.12 ± 2.71 ^{g, i}	9.60 ± 3.41 ^{h, j}
Illness perceptions (IP) (Mean ± SD) ^{b, ***}	37.13 ± 11.06	48.33 ± 8.39 ^{f, g, h}	41.72 ± 6.23 ^{f, i, j}	27.63 ± 9.87 ^{g, i, k}	34.78 ± 8.07 ^{h, j, k}
Consequence IP ^{b, ***}	4.88 ± 2.91	7.30 ± 2.55 ^{f, g, h}	5.13 ± 2.43 ^{f, i}	2.94 ± 2.60 ^{g, i, k}	5.20 ± 2.55 ^{h, k}
Timeline IP ^b	8.20 ± 2.44	8.07 ± 2.49	8.51 ± 1.85	7.53 ± 2.98	8.73 ± 2.18
Personal control IP ^b	3.53 ± 2.51	3.73 ± 3.06	4.13 ± 2.31	3.20 ± 2.40	3.00 ± 2.33
Treatment control IP ^{b, ***}	1.93 ± 2.03	2.57 ± 2.54 ^h	2.57 ± 1.82 ^j	1.75 ± 2.01	0.83 ± 1.34 ^{h, j}
Identity IP ^{b, ***}	4.51 ± 2.91	7.17 ± 2.30 ^{f, g, h}	5.17 ± 2.41 ^{f, i, j}	2.35 ± 2.50 ^{g, i}	4.40 ± 2.43 ^{h, j}
Concern IP ^{b, ***}	6.85 ± 2.82	8.63 ± 2.09 ^g	7.38 ± 2.11 ⁱ	4.98 ± 3.22 ^{g, i, k}	7.20 ± 2.31 ^k
Coherence IP ^{b, *}	2.79 ± 2.52	3.53 ± 3.56	3.15 ± 1.91 ^j	2.69 ± 2.65	1.88 ± 1.84 ^j
Emotional representation IP ^{b, ***}	4.45 ± 3.32	7.33 ± 2.71 ^{g, h}	5.68 ± 2.56 ^{i, j}	2.20 ± 2.99 ^{g, i}	3.55 ± 2.72 ^{h, j}

Self-efficacy (Mean ± SD) ^{c, **}	33.24 ± 5.96	31.30 ± 6.65 ^{h, j}	32.02 ± 6.18 ^l	33.47 ± 6.11	36.00 ± 3.64 ^{h, j}
Health literacy (Mean ± SD) ^d	3.72 ± 2.02	3.13 ± 1.94	3.96 ± 1.91	3.80 ± 2.11	3.75 ± 2.08
Inadequate		7 (23.3%)	7 (13.2%)	7 (17.5%)	10 (19.6%)
Marginal		11 (36.7%)	10 (18.9%)	9 (22.5%)	9 (17.6%)
Adequate		12 (40.0%)	36 (67.9%)	24 (60%)	32 (62.7%)
Age	58.74 ± 12.84	55.17 ± 14.00	57.85 ± 11.48	59.04 ± 13.92	62.20 ± 11.73
White ^{**}	118 (67.8%)	12 (40.0%)	38 (71.7%)	29 (72.5%)	39 (76.5%)
Female	100 (57.5%)	18 (60.0%)	30 (56.6%)	20 (50.0%)	32 (62.7%)
Education higher than high school	108 (62.1%)	15 (50.0%)	32 (60.4%)	35 (68.6%)	26 (65.0%)
Education					
Completed 8 th grade or less	4 (2.3%)	1 (3.3%)	0 (0.0%)	1 (2.0%)	2 (5.0%)
Some high school	15 (8.6%)	5 (16.7%)	3 (5.7%)	5 (9.8%)	2 (5.0%)
High school graduate or GED	47 (27.0%)	9 (30.0%)	18 (34.0%)	10 (19.6%)	10 (25.0%)
Some college or technical school	67 (38.5%)	10 (33.3%)	14 (26.4%)	26 (51.0%)	17 (42.5%)
College graduate	24 (13.8%)	3 (10.0%)	12 (22.6%)	6 (11.8%)	3 (7.5%)
Graduate degree	17 (9.8%)	2 (6.7%)	6 (11.3%)	3 (5.9%)	6 (15.0%)

Number of medications (Mean \pm SD) ^{***}	7.77 \pm 3.89	9.07 \pm 4.21 ^g	8.19 \pm 4.03 ^l	5.80 \pm 2.86 ^{g, l, k}	8.75 \pm 3.75 ^k
Number of illness (Mean \pm SD) ^{**}	3.86 \pm 1.82	4.50 \pm 2.03 ^g	3.89 \pm 1.96	3.22 \pm 1.47 ^{g, k}	4.28 \pm 1.66 ^k
Duration of diabetes diagnosed (Mean \pm SD) [*]	9.58 \pm 7.08	8.75 \pm 5.79	9.25 \pm 6.30	8.03 \pm 7.14 ^k	12.61 \pm 8.13 ^k
HbA1c level [*]	7.66 \pm 1.64	8.31 \pm 2.14 ^g	7.86 \pm 1.58	7.17 \pm 1.32 ^g	7.52 \pm 1.51
Health status ^{e, **}	2.64 \pm 0.80	2.13 \pm 0.90 ^{f, g}	2.72 \pm 0.77 ^f	2.86 \pm 0.75 ^g	2.65 \pm 0.70

^a Self-reported medication adherence was measured with the 8-item Morisky Medication Adherence Scale. Use of the ©MMAS is protected by US Copyright laws. Permission for use is required. A license agreement is available from: Donald E. Morisky, MMAS Research LLC 14725 NE 20th St. Bellevue WA 98007 or from dmorisky@gmail.com.

^b Higher scores indicate higher specific illness perceptions. Personal control, treatment control, and coherence are reverse scored.

^c Higher scores indicate higher levels of self-efficacy.

^d Health literacy was measured with the Newest Vital Sign (NVS).

^e One item on a 5 point scale. Higher scores indicate better self-reported health status.

^{f-k} Significant differences based on the post-hoc analysis.

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Table 2 Beliefs, psychosocial and clinical characteristics of the clusters

	Clusters with non-adherence behavior		Clusters with adherence behavior	
	Cluster 1 (Ambivalent)	Cluster 2 (Skeptical)	Cluster 3 (Indifferent)	Cluster 4 (Accepting)
Medication Adherence	Low adherence	Low adherence	High adherence	High adherence
Beliefs in medicines	High NB	Low NB	Low NB	High NB
	High CB	High CB	Low CB	Low CB
Illness perceptions	High IP	High IP	Low IP	Low IP
Self-efficacy	Low SE	Low SE	High SE	High SE
Health literacy	Low HL	High HL	High HL	High HL
Glycemic control	High HbA1c	High HbA1c	Low HbA1c	Low HbA1c
Illness perception domains	High Consequence	High Consequence	Low consequence	High consequence
	High treatment control	High treatment control	Low treatment control	Low treatment control
	High identity	High identity	Low identity	Low identity
	High concern	High concern	Low concern	High concern
	High coherence	High coherence	Low coherence	Low coherence

High emotional representation	High emotional representation	Low emotional representation	Low emotional representation
