Figure S1. Calcium and behavioral imaging in agarose microchambers. Related to Figure 1 and Figure 2. Shown are fluorescence images of adult worms expressing GCaMP3 in the sleep-active neuron RIS. The pictures are false-colored to visualize calcium activity. The border of the agarose microchamber is marked by a white dotted line. The asterisk indicates the worm's nose, the arrow the sleep neuron RIS. The left panels show wake worms, the right panels sleeping worms. Note the relaxed body posture and increased RIS GCaMP intensity during sleep. The top panels show worms feed on OP50. The bacteria are visible due to their auto-fluorescence. On the bottom panels, the worms are starved.

Figure S2. Distribution of sleep bout lengths and their contribution to total sleep amount. Related to Figure 1 and Figure 2. Shown are number of bouts per animal per hour as well as cumulative sleep amount as a function of bout length to show which bout lengths contribute how much to total sleep amount. Note that most sleep occurs in shorter bouts except for dauer larvae and *daf-2(-)*, which show also longer sleep bouts that contribute substantially to total sleep amount. (**A-B**) Adults with growth medium, (**C-D**) starved adults, (**E-F**) L1 lethargus, (**G-H**) starved L1 arrested, (**I-J**) dauer without food, (**K-L**) adults feeding on starved bacteria and dauer pheromone, (**M-N**) *daf-2(-)* adults feeding on starved bacteria.

Figure S3. Control experiments for characterizing larval sleep during starvation-induced arrest. Related to Figure 3. (**A-B**) ASH and mechano-sensory neurons activation during wake in arrested L1 larvae. During wake, there is no detectable action from ASH nociceptive neurons (**A**) or *mec-4* expression mechano-sensory neurons (**B**). RIS activity is shown in red (control without ATR in light red), speed in black (control without ATR in gray), and the fraction of sleeping animals in blue (control without ATR in light blue). (**A-C**) ASH and mechano-sensory neurons activation during wake in arrested L1 larvae. During wake, there is no detectable action from ASH nociceptive neurons (**A**), *mec-4* expression mechano-sensory neurons (**B**) or from noxious blue light irradiation (**C**). RIS activity is shown in red (control without ATR or without stimulation in light red), speed in black (control without ATR or without stimulation in gray), the fraction of sleeping animals in blue (control without ATR or without stimulation in light blue), green light illumination in green and noxious blue light irradiation in teal. (**D-E**) *flp-11::ArchT* activation efficiently reduces RIS activity and consequently inhibits sleep. (**D**) Complete documentation of homeostasis experiment. RIS activity is shown in red (control without ATR in light red), speed in black (control without ATR in gray), and the fraction of sleeping animals in blue (control without ATR in light blue). (**E**) Statistical comparison of the different 1h long periods. During green light illumination the sleep fraction was reduced by 62.0 ± 0.5%, ***$p < 0.001$, and after illumination the sleep fraction increased by 52.5 ± 0.1%, ***$p < 0.001$, compared to the sleep fraction before the illumination. Comparisons were made using the paired Wilcoxon rank test. n = 32 worms.

Figure S4

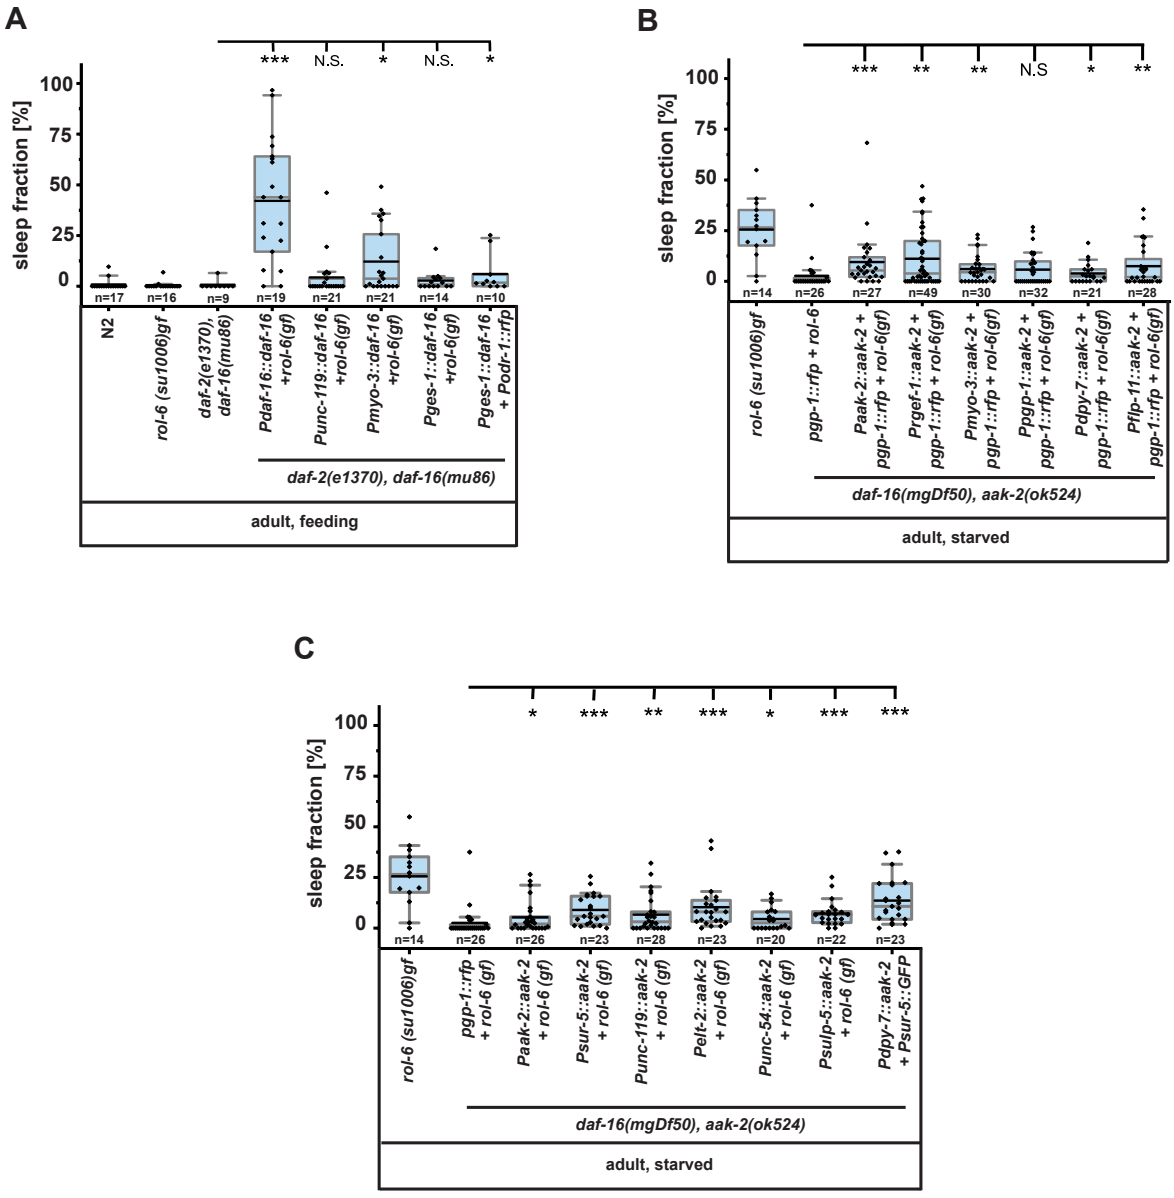

Figure S4. Rescue experiments for FoxO and AMPK. Related to Figure 4. (A) Rescue experiments using inserted transgenes of *daf-16* shows weak rescue only in muscle and inconsistent recue in the intestine. *daf-16* was expressed from its endogenous promoter, in neurons (*Punc-119*), in body wall muscle (*Pmyo-3*) and in the intestine (*Pges-1*). Most transgenes carry a *rol-6(su1006)* transformation marker, the roller phenotype does not affect sleep, Median sleep fraction was 0% for wild type N2 and *rol-6(su1006)*, the same data is displayed in panel B. Median sleep fraction for rescue experiments was 0% for the background genotype *daf-2(e1370)/daf-16(mu86)*, 44% for rescue using the endogenous promoter (***$p < 0.001$), 0 % for pan-neuronal rescue, 4% for muscle rescue (*$p < 0.05$), 1% and 2% for intestinal rescue dependent on the

transgenic array ($p = 0.11$ and $*p < 0.05$, respectively). *daf-2(e1370)/daf-16(mu86)* data was taken from DIC movies collected for the same animals that were analyzed for Figure 4C and is the same as used in Figure S4B. (B) Rescue experiments using extrachromosomal transgenes of *aak-2* shows weak rescue across tissues, which was expressed from its endogenous promotor, in neurons (*Prgef-1*), in body wall muscle (*Pmyo-3*), in the intestine (*Ppgp-1*), in the hypodermis (*Pdpy-7*), and in RIS (*Pflp-11*). Transgenes carry a *rol-6(su1006)* and intestinal red fluorescence (*pgp-1::rfp*) transformation marker. For comparison, a wild type background is shown, which only expresses a transformation marker. It is the same comparison as shown in Figure S4D. Median sleep fraction was 0% for *daf-2(mgDf50)/aak-2(ok524)* carrying the transformation markers only, 5% for rescue by endogenous promoter ($***p < 0.001$), 4% for pan-neuronal rescue ($**p < 0.01$), 4% for muscle rescue ($**p < 0.01$), 0% for intestine, 2% for hypodermis ($*p < 0.05$), and 2% for RIS ($**p < 0.01$). (C) Additional rescue experiments using extrachromosomal transgenes of *aak-2* with different transformation markers and promoters shows weak rescue across tissues, which was expressed from its endogenous promotor, ubiquitously (*Psur-5*), in neurons (*Punc-119*), in the intestine (*Pelt-2*), in muscle (*Punc-54*), in the hypodermis (*Pdpy-7*), and in the excretory cell (*Psulp-5*). Transgenes carry a *rol-6(su1006)* or other transformation marker. For comparison, a wild type background is shown, which only expresses a transformation marker. It is the same comparison as shown in Figure S4C. Median sleep fraction was 0% for *daf-2(mgDf50)/aak-2(ok524)* carrying the transformation markers only, 2% for rescue by the endogenous promoter ($*p < 0.001$), 6% for ubiquitous expression ($***p < 0.001$), 3% for pan-neuronal rescue ($**p < 0.01$), 8% for intestine ($***p < 0.001$), 3% for muscle rescue ($*p < 0.05$), 7% for the excretory cell ($***p < 0.001$) and 11% for hypodermis ($***p < 0.001$). The low rescue effects obtained after using the endogenous *aak-2* and *sur*-5 promoters are consistent with previous measurements using these transgenes. Perhaps the weak rescue can be explained by weak transmission of the array[S1]. The number of worms assayed (n) is displayed underneath each box plot. For statistical comparisons, Mann-Whitney U test was used to calculate the p value and significance was confirmed by Benjamini-Hochberg Procedure for multiple comparisons.

Figure S5. Sleep is required to survive larval starvation. Related to Figure 5. Supplementary figure containing additional replicates related to Figure 5. The biological replicates are indicated as different batches with different lines or symbols. **(A)** Adult lifespan of feeding wild type (blue) and *aptf-1* mutants (red). No consistent significant difference could be shown. **(B)** Lifespan of feeding wild type (blue) and RIS(-) (yellow) adult worms were not significantly different for the two replicates. **(C)** No significant difference was detected for the starved adult lifespan of wild type and *aptf-1(gk794),* **(D)** and also not between starved wild type and RIS(-) adult worms. **(E-F)** L1-arrested starved *aptf-1(gk794)* mutants and RIS ablated worms show substantially reduced survival in all replicates latest from day 16. **(G-H)** All replicates of arrested L1 *aptf-1(gk794)* and RIS-ablated worms showed a significant decline in the ability to re-enter development compared to N2 worms when fed. Data are significant latest from day 12. **(I)** Starved arrested L1 *aak-1(tm1944)/aak-2(ok524)/daf-16(mgDf50)*/*aptf-1(gk794)* quadruple mutants showed no reduced lifespan compared to *aak-1(tm1944)/aak-2(ok524)*/*daf-16(mgDf50)* triple mutants. **(J)** *aptf-1(gk794)* and RIS(-) L1s arrested on FUdR have a decreased survival compared to wild type worms in the presence of food. The corresponding data, significance values and tests for all replicates are shown in Tables S1-S5.

Figure S6

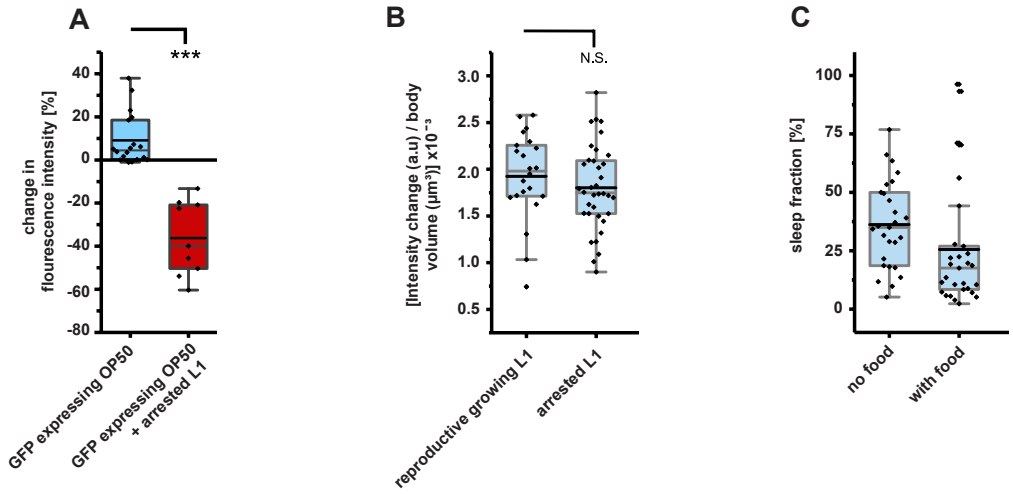

Figure S6. Arrested L1 larvae consume bacteria. Related to Figure 5. (**A**) The fluorescence intensity change of GFP expressing OP50 was measured in agarose microchambers. The two-day reduction in fluorescence is significantly different comparing microchambers containing arrest L1s to microchambers without worms (with worms: 36.3 ± 5.8% decrease, n = 9 microchambers, without worms: 9.1 ± 2.8% increase, n = 18 microchambers, ***$p < 0.001$, Mann-Whitney U test). **(B)** Arrested L1 larvae consume similar amounts of bacteria as reproductive growing L1 worms. The change in fluorescence intensity of OP50 GFP bacteria within 200 min was normalized to worm volume, to compensate for variability in size, which is caused by increased growth in non-arrested worms. The time window was chosen because size differences were still modest. No significant difference in bacterial consumption was detected for reproductive growing L1s (with a mean of $1.92x10^{-3}$ arbitrary units/μm^3, n = 22) and FUdR-arrested L1s (mean = $1.8x10^{-3}$ arbitrary units /µm3, n = 36), p = 0.33, two-sample t-test. (C) Sleep fraction of starved and feeding FUdR arrested L1s in wildtype. Starved L1s with FUdR (4 to 5 days-old) had a median sleep fraction of 34.9%, n = 27. Median sleep fraction of the feeding L1s with FUdR (4 to 5 days-old) is 17.5%, n = 29.

Table S1

Lifespan of adult, feeding					
Strain	Experiment batch (in Figure)	# scored/ # total	Mean of lifespan (days)	Compared to	*p* value against control (log-rank test)
wildtype N2	1 (Figure 5A)	44/50	14.64

Table S6. Number of replicates for all experiments. Related to all Figures and Supplemental Figures.

Table S7

Primer name	Primer sequence 5'-3'
aak-1(tm1944)	
890	ACTGTTCCGAGTCCTTTCATTC
891	TTCCCTTTCTTCGCTCACTTTT
892	ATGGAACTGTGTATCGGCCA
aak-2(ok524)	
893	ATCGCCAAATTATGCTGCCC
894	GGCAGGGTTCCACAAAGAAG
895	AAGGAGACACTCGGAGTTGG
aptf-1(ok974)	
48	CGACAATCTTCCCAAAGACC
49	CGGATCGATTGCTAGAGAGG
50	GCTTGGACGGCTTTAGTTGA
*daf-2(e1370)**	
519	CGGGATGAGACTGTCAAGATTGGAGATTTCGG
520	CAACACCTCATCATTACTCAAACCAATCCATG
daf-16(mgDf50)	
636	AGGTCAGAGTTCTAGGCGTAAA
637	CGGTTCCAGCAATTCCAAGT
638	AGTGGATTCTGAGCACACGA
daf-16(mu86)	
468	AAAGAGCTCGTGGTGGGTTA
469	TCGCGCCTTTGTCTCTCTAT
470	AGTGTCGAGTGAAGGGAGC
sir-2.1(ok434)	
1107	GTTTGATCACTCCTTCGCAAC
1108	TCCCAGGACAGTTCGTACC
1109	GCGGAAATGGCAGAAGTAGT
daf-18(ok480)	
1090	AGCATGGACTTCAACGATACAA
1091	GAATGCCAGATTGCCGAACA
1092	CGGTGGTCCATTTGAGATACC

Table S7. List of PCR primers used for Duplex PCR Genotyping. **Related to STAR Methods.** *The *daf-2* mutant allele was identified using restriction with NcoI-HF (in CutSmart Buffer, New England Biolabs).
