

Figure S7. Average relative abundance of genera in the anterior nares bacterial communities of samples taken during and either before or after a picornavirus infection (PVI) within the same children.

Six children provided nasal swabs before and during PVI (five samples one month and one sample two months before PVI) (left); Eight children provided nasal swabs during and after PVI (seven samples one month after and one sample two months after PVI) (right); Bacteria with an average relative abundance below 1% and unclassified bacteria were summarized as “Others”.
