Supplemental Figure 1. Opines induce transfer of Ti plasmids because they induce transcription of traR. The operon colored black is an operon that is inducible by the conjugative opine. The *tra* regulon is light grey and the plasmid replication and partitioning genes are dark grey. The genes and proteins involved in regulation of transfer are as follows: *traR*/TraR, black dots on a white background; *traM*/TraM, diagonal stripes; *traI*/TraI, white; and a transcriptional regulator that also senses the conjugative opine, horizontal stripes; Agrobacterium autoinducer (AAI) is indicated by σ , while the conjugative opine is indicated by asterisks (*). Promoters are indicated by "P" and transcriptional direction is indicated by the arrows. (A) Under non-inducing conditions TraM binds to the low levels of TraR that are produced thereby inactivating the transcriptional regulator. (B) Under inducing condition the presence of the conjugative opine induces transcription of an opine-regulated operon, including *traR*. In this manner TraR titrates the effects of TraM and, as long as the population has reached its critical threshold and enough AAI is available, TraR can form active dimers and activate transcription of the *tra* regulon.

Supplemental Figure 2. TmsPs aligns with the C terminal domain of TraR proteins. The drawing represents the N terminal AAI binding domain and C terminal DNA binding domain of TraR proteins. The region of TraR that interacts with TraM is also located at the C terminal region. TmsPs and the C terminal region of three TraR proteins were aligned using Clustal W. Invariant residues are purple, conserved residues are blue, while residues that are similar are pink. Above the aligned sequences, the residues of TraR_{pTiC58} important for TraR-TraM interaction (Luo *et al.*, 2000, Qin *et al.*, 2007) are indicated with a black five-

pointed star, while the residues of TraR_{pNGR234a} that are sequence-specific for the TraR-TraM interaction (Chen *et al.*, 2007) are indicated by a white 4-pointed star.

Supplemental Figure 3. TmsP has three potential start sites. The nucleotide sequence of *tmsP* and 100 nucleotides upstream of the gene are shown. The three potential start sites are labeled and colored in green, while the stop codon is colored red.

Supplemental Figure 4. A putative MrtR-binding box is encoded in the intergenic sequence between mrtR and mocC. (A) *mrtR* and *mocC* are divergently transcribed. The sequence of the nucleotides between the two genes is shown with the start codons for each gene colored in green. The putative MrtR-binding box is a 14 base pair palindromic sequence and is colored red. (B) An alignment of the DNA binding sites for the GntR regulator ExuR from *Escherichia coli* (Rigali *et al.*, 2002), and the putative MrtR box of pAoF64/95.

Supplemental Figure 5. MocR does not regulate transfer of pAoF64/95. NTL4 harboring pAoF64/95 and the *mocR* mutant, NTL4(pAoF64/95Δ*mocR*) were assessed for conjugative transfer when grown in AB minimal medium with mannitol (light grey) or mannopine (dark grey) as the primary source of carbon.
