S4 Table: Inhibitory effects of peptide combinations on the activation of platelets: comparison with peptides at single concentrations. A visual summary of this data is shown in Fig 3. Platelets were co-incubated with peptides (4 μ M for pal-peptides; 10 μ M for tat-peptides) individually or in combination, and then activated with TRAP (2 μ M). * $P \leq 0.05$, two-tailed t-test: this is not a formal test of the probability of observing the association by chance, but is used here as a scale on which to highlight the most interesting effects.
