

BMJ Open

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email info.bmjopen@bmj.com

ABSTRACT

Introduction: Genetic testing for hypertrophic cardiomyopathy (HCM) in the era of genomics brings unique challenges for genetic counselling. The number of genes routinely included in an HCM gene panel has increased markedly, many with minimal if any robust evidence of gene-disease association. Subsequently there is a greater chance of uncertain genetic findings. The responsibility of communicating this information with at-risk relatives lies with the index case (proband). We have developed a communication aid to assist with the delivery of genetic results to the proband. We have previously shown the aid is feasible and acceptable, and have now developed a study protocol for a randomised controlled trial of a genetic counsellor-led intervention incorporating the communication aid.

Methods and Analysis: This is a prospective randomised controlled trial. We will investigate the impact of a genetic counsellor-led intervention to return proband gene results using a custom designed communication aid. We aim to improve knowledge and empowerment. The primary outcome of this trial is the ability and confidence of the proband to communicate genetic results to at-risk relatives. Secondary outcomes will assess genetic knowledge, satisfaction with services, outcomes from genetic counselling and psychological adaptation to genetic information.

Ethics and Dissemination: This study has been approved by and is in strict accordance with the Sydney Local Health District Ethics Review Committee (X16-0030; 22/01/2016; version 1). Results from this trial will be prepared as a manuscript and submitted to peer-reviewed journals for publication as well as submission for presentation at national and international meetings.

Registration Details: This trial is registered with the Australian New Zealand Clinical Trials Registry: ACTRN12617000706370

STRENGTHS AND LIMITATIONS

- This study will assess the effectiveness of a communication aid to improve the ability and confidence of patients with hypertrophic cardiomyopathy (HCM) to communicate genetic test results with their at-risk relatives.
- The results of this trial will inform genetic counselling practice for HCM genetic testing, as well as be broadly applicable for other inherited heart diseases.
- Limitations include the generalisability of our findings, which are true for a specialised multidisciplinary clinic where the intervention was performed but may not be representative of the broader HCM population undergoing genetic testing.
- As genomic technologies continue to evolve, uncertainty and complexity of genetic findings will likely increase over time.

INTRODUCTION

Background and rationale

Genetic testing in the era of genomics brings unique challenges for the genetic counselling of families. Hypertrophic cardiomyopathy (HCM) is a clinically heterogeneous inherited heart disease characterised by unexplained left ventricular hypertrophy in the absence of a loading condition such as hypertension.¹ With a prevalence of 1 in 200-500, it is one of the most common inherited heart diseases and clinical manifestations can range from asymptomatic through to heart failure or sudden cardiac death.² In the setting of HCM, genetic testing of the index case (proband) can provide invaluable information by allowing at-risk relatives the opportunity to undergo cascade genetic testing to look for the presence or absence of the family-specific variants.³ The first step is often the most challenging, requiring identification of a variant for which there is sufficient evidence of causation.

Genetic counselling is a critical aspect of the process, not just for genetic testing, but also for understanding inheritance risks, characterisation of the family history and information and emotional support.⁴ Within a clinical setting, pre- and post-test genetic counselling should include discussion of inheritance risks and clinical screening guidelines for at-risk relatives.⁵ This allows asymptomatic at-risk relatives to make proactive, informed decisions regarding their risk, including family planning decisions.

How a patient understands and communicates this genetic information to their at-risk relatives is critical to ensuring patients' get the most value out of genetic testing. This task of communication relies on the proband within the family. Current Australian practice and privacy laws dictate that in most cases the health care provider does not make contact with relatives to disclose risk information. Therefore, it follows that in order to communicate genetic results or risk information the proband must have adequate understanding of the

1 information they have received from their healthcare provider. Several studies indicate this
2
3 may be problematic, and some individuals may not retain or understand the information
4
5 presented to them.⁶
6
7
8
9

10 **Existing knowledge**

11
12 Currently literature estimates between 20-40% of relatives remain unaware of relevant
13
14 genetic information and do not act on information even when they have reportedly been
15
16 informed of their risk.⁷⁻⁹ Many factors have been identified which influence family
17
18 communication about genetic risk, including complicated family dynamics, guilt, anxiety
19
20 and gender, however are difficult to target as areas for improvement within the context of
21
22 one or two genetic counselling sessions.^{7 8 10 11} There are stages within the genetic
23
24 counselling process, where communication of genetic results and uptake of appropriate
25
26 screening may be influenced.
27
28
29
30
31

32 Our group and others have shown some of the barriers that can negatively impact on
33
34 family communication. In a qualitative study of HCM patients undergoing comprehensive
35
36 genetic testing, many patients reported uncertain results to be conveyed less amongst
37
38 families.¹² Further, these results are often misunderstood. For example, amongst this
39
40 cohort, probands with uncertain results perceived these results as falsely reassuring or
41
42 conversely suggests their disease is 'worse' or 'different'. This led to a misunderstanding
43
44 that their result was not heritable and therefore communication with relatives did not
45
46 occur.¹² Supporting these findings, the general genetics literature highlights that risk
47
48 perception and understanding of results though varied, can be poor, inaccurate and
49
50 incomplete.^{13 14}

There is evidence for the effectiveness of a genetic counsellor in addressing some of the communication and knowledge barriers.¹⁵⁻¹⁷ One key area for intervention is during the post-test genetic counselling session. Genetic and risk information can be difficult to understand and explain clearly and as a consequence, the patient may not gain sufficient knowledge and lack confidence to convey these key messages to at-risk relatives.¹² Further, it is recognised patients deliberate on the appropriate time to communicate genetic information and make decisions regarding which relatives the information is pertinent to, regardless of the recommendation of professionals.^{7 18 19} Few resources exist which aim to facilitate effective communication to at-risk relatives. We therefore hypothesise that improving knowledge of an HCM genetic diagnosis will have a positive impact on communication to at-risk relatives, as well as genetic knowledge, satisfaction with services, outcomes from genetic counselling and psychological adaptation to genetic information.

Utility of a communication aid

When asked about family communication, most patients report families should communicate risk amongst themselves with varying levels of support from their healthcare providers.^{14 17 20} In addition, there is evidence for the effectiveness of genetic counselling to assist with this process.^{15 16 20} Hodgson et al. published a randomised controlled trial assessing the impact of a genetic counselling phone intervention on communication of genetic information within families.²¹ They found no significant difference between the intervention and control group when measuring contact with genetic services, though in sub-analyses of the high-risk children group, the primary outcome was significantly improved. Importantly, the primary outcome measure was contact with a genetic service, which can be difficult to ascertain and may not be the most accurate measure of effectiveness or a direct reflection of communication efforts.

1 Resources such as decision and communication aids, or family letters, may provide
2 additional support to this process, though more data is needed regarding efficacy.^{15 19 21 22}

3
4
5 Decision or communication aids are tools specifically designed to support patients with
6 decision making and unmet information needs. There is evidence for the effectiveness of
7 an aid with regard to improved knowledge and accuracy of risk perceptions.²³⁻²⁵ Further,
8 most health information is written which may not be the most effective health
9 communication method. Communication and decision aids provide a format to include
10 visual elements that may improve comprehension, recall and comfort with the information,
11 particularly when health literacy may be an issue.

23 **Need for a trial**

24
25 Overall, the literature highlights that probands require additional support to understand and
26 communicate genetic results. The rationale for this study is the critical gap in supporting
27 patients' comprehension and consequent communication of genetic risk to at-risk relatives.
28
29 Though genetic counsellors are specifically trained in delivering genetic information,
30 information needs of patients are not always met and communication amongst at-risk
31 relatives can be suboptimal. As genetic test results become increasingly complex, an
32 evidence-based approach to supporting patients with genetic knowledge and risk
33 communication should be explored.

45 **STUDY AIMS AND OUTCOMES**

46
47 The aim of this randomised controlled trial is to determine if a genetic counsellor-led
48 intervention using a communication aid for the delivery of HCM genetic test results
49 improves the ability and confidence of the proband to communicate genetic results to at-
50 risk relatives compared with current clinical practice.

1. The primary outcome is the ability and confidence of the proband to communicate genetic results to at-risk relatives, measured at 2 weeks post-intervention.
2. Secondary outcomes will assess genetic knowledge, satisfaction with services, patient reported outcome of genetic counselling and psychological adaptation to genetic information, measured at 2 weeks post-intervention.
3. As a longer-term outcome, we will systematically assess and document family communication as reported by the proband measured by phone calls at one, three and six monthly intervals. The researcher conducting these phone calls will not be blinded to the treatment arm of the participant. These phone calls will be conducted and analysed after collection of the primary and secondary outcomes data. This is to prevent interference with results because the phone calls themselves may serve as a family communication intervention.

METHODS AND ANALYSIS

Trial design

This is a prospective randomised controlled trial. The protocol is reported in accordance with the SPIRIT statement, which provides recommendations for a minimum set of scientific, ethical and administrative elements that should be addressed within a clinical trial protocol.²⁶ All items from the World Health Organization Trial Registration Data Set are listed in Table 1. Consecutive HCM patients will be invited to participate when they are notified on the phone that their genetic result is ready to be returned. Once written consent is obtained they will be randomised to receive their genetic result via the intervention or control arm of the study (Figure 1).

Study setting

This trial will be carried out within a specialised multidisciplinary HCM clinic. This incorporates the expertise of specialist cardiologists and cardiac genetic counsellors.²⁷ Patients with HCM attending these clinics at Royal Prince Alfred Hospital will be invited to attend.

Eligibility criteria

HCM probands with a genetic result ready for return are eligible. Participants must be aged 18 years or older, with sufficient written English skills as nominated by the participant. Genetic testing is performed as part of a research study, or commercial laboratory as previously published.^{28 29} All identified variants are classified in the same manner, as per current clinical standards and guidelines.³⁰ Recruitment commenced in November 2017 and is expected to end in November 2018. Participants will be invited to participate in the study during their routine pre clinic phone call conducted as normal

1 clinical process. Informed consent will be obtained by the cardiac genetic counsellor
2 present at the participants clinic consultation (supplementary material).
3
4
5
6
7

8 **Randomisation**

9
10 A randomised list was prepared using the Excel (Microsoft Office) “Random” function and
11 study participants who consent to the study are allocated the next number on the random
12 list. This number is linked to either control or intervention. A researcher not involved in the
13 study performs the randomisation.
14
15
16
17
18
19
20

21 **Sample size and power calculations**

22
23 Prior to commencement of the study, power calculations were performed using the results
24 from our published feasibility study.³¹ The primary outcome of this trial is the ability and
25 confidence of the proband to communicate genetic results to at-risk relatives. Data from
26 the feasibility study indicated 75% of participants communicated genetic results to at-risk
27 relatives. Assuming the control group communicates in 50% of cases, at a significance
28 level of 5% and 80% statistical power, a sample size of n=21 is required per group.
29
30
31
32
33
34
35
36
37

38 **Development of the custom communication aid**

39
40 We have developed a communication aid to assist with the delivery of genetic results to
41 the proband and support family communication. A pilot study demonstrating feasibility and
42 acceptability of this aid has been previously reported.³¹ In brief, development of the aid
43 involved review of the literature alongside multidisciplinary meetings. Development was a
44 multistep process and on the basis of meeting outcomes, literature review and empirical
45 evidence from the multidisciplinary team. The aid addresses:

3. Overview of the process involved in classification of a genetic variant
 4. Implications for at-risk relatives including family screening recommendations

Control arm

Those within the control arm of the study will receive their result via normal clinical practice. There are currently no evidence-based guidelines for return of comprehensive genetic test results within the multidisciplinary clinic setting. Normal clinical practice typically involves return of a genetic result either by the cardiologist or genetic counsellor. Return of the result is usually performed following clinical cardiology review, which is often the primary purpose of the consult. In the majority of cases a genetic counsellor is present.

Intervention arm

Those randomised to the intervention arm will be allocated a separate appointment time after clinical review with their cardiologist, where they will see the cardiac genetic counsellor who will return their genetic result using the communication aid.

The communication aid covers the process of genetic testing and risk from diagnosis of HCM through to the implications of a genetic result for at-risk relatives (Figure 2). There is a section in the aid under 'Results', which goes through the meaning of each category of genetic result. These include an indeterminate result (no variant identified), a variant of uncertain significance and a likely pathogenic/pathogenic result (Figure 3). The genetic counsellor returning the genetic result will mark the appropriate category of result, which applies to the patient in front of them. The genetic counsellor will return the genetic result, and then go through the communication aid, referencing the individual result and specific recommendations for the rest of the family. There will be an opportunity to ask questions,

1 and the genetic counsellor will write the specific recommendations for each family member
2
3
4 in the box provided at the end of the communication aid (Figure 4).
5
6
7

8 **DATA COLLECTION AND OUTCOMES**

9
10 Both the primary and secondary outcomes will be measured at a single time point (2-
11 weeks post intervention) using a survey comprised of a number of previously published
12 and validated scales. A number of demographic questions will also be asked within the
13 survey. The survey will be available online via qualtrics (<https://www.qualtrics.com/>) with a
14 direct link sent to participants. For those who prefer a hard copy it will be posted with a
15 return envelope. The survey will be sent two weeks after return of genetic results.
16
17 Evidence regarding the most appropriate time between genetic result disclosure and family
18 communication is lacking. However, given the risk of arrhythmia and sudden death within
19 the inherited heart disease context, two weeks post result disclosure was considered by
20 the study team to be an appropriate time point to send the survey.²⁵ Return of the survey
21 is followed up on a fortnightly basis.
22

28
29
30
31
32
33
34
35

36 **Primary outcome**

37
38 The primary outcome of this trial is the ability and confidence of the proband to
39 communicate genetic results to at-risk relatives. This will be measured at a single time
40 point, administered two weeks after return of genetic results. Ability and confidence will be
41 assessed by two measures and then combined into a binary outcome. The certainty sub-
42 scale of the Psychological Adaptation to Genetic Information (PAGIS) scale will measure
43 confidence with genetic knowledge.³² This sub-scale measures the patients' perception
44 and confidence in their genetic knowledge and the items from this sub-scale are listed in
45 Table 2. Subsequent ability to pass this information on will be measured by the number of
46 at-risk relatives informed of genetic results by the proband. We will average the scores
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1 from both measures to determine a final score. The calculations used to determine this
2 cut-off are illustrated in Table 3. The final score will be converted to a binary outcome of
3 fair versus poor ability and confidence to communicate genetic results to at-risk relatives.
4
5
6 This outcome has been specifically designed for this study.
7
8
9

10
11
12 Factors that influence communication of genetic results to at-risk relatives are
13 multidimensional. For this reason, we chose this combination approach to more broadly
14 reflect the communication process. Many studies rely on single and linear measures of
15 communication such as contact by relatives with genetics departments or self reported
16 communication with at-risk relatives only. To overcome this, we aimed to incorporate a
17 multidimensional approach that included the probands confidence regarding their
18 knowledge of genetics alongside the action linked to this knowledge, being the
19 communication to relatives. This will aim to determine consistency between the probands
20 confidence with genetic information against their self-reported percentage of immediate
21 family members informed
22
23
24
25
26
27
28
29
30
31
32
33

34
35
36 The certainty sub-scale of the Psychological Adaptation to Genetic Information Scale
37 (PAGIS) will be used to measure confidence with genetic knowledge as described
38 above.³² Guided by grounded theory in patient perspectives of genetic counselling and the
39 Roy Adaptation to Genetic Information Model, the 26-item PAGIS scale allows for
40 evaluation of the efficacy of genetic counselling.^{32 33} The scale aims to incorporate the
41 multidimensional adaptation to genetic information and comprises of five domains which
42 include; a) non-intrusiveness, b) support c) self-worth, d) certainty and e) self-efficacy.³²
43
44
45
46
47
48
49
50
51 Evidence for the utility of this scale has been published and illustrates its potential use for
52 assessing genetic counselling interventions.³²
53

56
57
58
59
60

Secondary outcomes

The survey comprises three additional scales to assess primary and secondary outcomes, a number of questions regarding communication with relatives, as well as a number of demographic questions.

Genetic knowledge will be assessed using an amended version of the Breast Cancer Genetic Counseling Knowledge Questionnaire (BGKQ).^{33 34} This scale was originally developed to assess knowledge of information typically included in genetic counselling for breast cancer. The original scale was a 27 item questionnaire including statements regarding genetics such as '*50% (half) of your genetic information was passed down from your mother*' and participants were asked if the statement was true or false. Items in the original scale were empirically derived from detailed content analysis of breast cancer genetic counselling sessions. The original scale demonstrated a high content validity with cronbachs $\alpha = 0.92$, with demonstrated ability to discriminate between patients before and after genetic counselling sessions.³⁴ We have amended questions to reflect the HCM context and 10 items were included.

Satisfaction with services received will be assessed using the widely used Satisfaction with Genetic Counseling Scale (SGCS).³⁵ The original questionnaire was designed to assess three dimensions of patient satisfaction: instrumental, affective and procedural.^{33 35} This survey will use an amended version of the 12 item short form of the survey.

The genetic counselling outcome scale (GCOS-24) will be used to assess patient reported outcomes of genetic counselling.³⁶ The questionnaire was designed to be used pre and post genetic counselling, though we have used it in the post counselling setting. The

1 authors of this scale used the construct of empowerment to summarise the patient derived
2
3 benefits from genetic counselling.
4
5
6
7

8 **Data management**

9
10 All data from the survey will be entered into Microsoft Excel. Patient identifiers will be
11 removed with study codes allocated. The primary researcher will be blinded to treatment
12 arm of the patient for analysis of the primary and secondary outcome data. A second
13 senior researcher and supervisor will oversee data storage and analysis. Data will be
14 stored in accordance with the Sydney Local Health District Ethics Review Committee and
15 Centenary Institute.
16
17
18
19
20
21
22
23
24

25 **Data analysis plan**

26
27 Data will be analysed using Prism (version 7.0) and SPSS (Version 23.0). We will compare
28 the primary outcome as a binary measure between the intervention and control group. We
29 will use chi-square analyses using $p < 0.05$ for statistical significance. For assessment of
30 secondary outcomes we will be guided by published scoring systems for the validated
31 scales to score genetics knowledge, satisfaction with services and genetic counselling
32 outcomes. Mean scores for each scale will be compared between the intervention and
33 control group and comparisons between the control and intervention group will be
34 analysed using unpaired t-tests for continuous data and chi-square analysis for categorical
35 data. Sub-group analysis will also be performed; specifically we will compare outcomes in
36 the study groups stratified by the gene result (i.e. causative, uncertain or indeterminate
37 results).

ACKNOWLEDGEMENTS AND FUNDING

CB is the recipient of an Australia Postgraduate Award (APA). CS is the recipient of a National Health and Medical Research Council (NHMRC) Practitioner Fellowship (#1059156). JI is the recipient of a National Heart Foundation of Australia Future Leader Fellowship (#100833).

We thank Yana Smagarinsky for her assistance with developing the communication aid and Katharine Morgan for graphic design of the communication aid.

AUTHOR STATEMENT

All authors contributed to the manuscript, specifically:

- (1) Substantial contributions to the conception or design of the work; or the acquisition, analysis, or interpretation of data for the work (CB, LY, CS, JI); AND
- (2) Drafting the work or revising it critically for important intellectual content (CB, LY, CS, JI); AND
- (3) Final approval of the version to be published (CB, LY, CS, JI); AND
- (4) Agreement to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved (CB, LY, CS, JI).

Table 1: Trial Registration Data

Primary registry and trial identifying number	Australian New Zealand Clinical Trials Registry: ACTRN12617000706370
Date of registration in primary registry	17/05/2017
Secondary identifying numbers	NA
Source(s) of monetary or material support	National Heart Foundation of Australia
Primary sponsor	The University of Sydney
Secondary sponsor	NA
Contact for public queries	Dr Jodie Ingles j.ingles@centenary.org.au
Contact for scientific queries	Dr Jodie Ingles j.ingles@centenary.org.au
Public title	Use of an aid to improve communication of genetic risk information to families with hypertrophic cardiomyopathy (HCM)
Scientific title	Use of a custom designed aid to improve communication of genetic results in families with HCM
Countries of recruitment	Australia
Health condition (s) or problem (s) studied	HCM
Intervention	Use of a custom designed aid to communicate HCM genetic test results
Key inclusion and exclusion criteria	HCM probands with a genetic result ready for return Participants must be aged 18 years or older Sufficient written English skills as nominated by the participant
Study type	Prospective randomised controlled trial
Date of first enrolment	25/11/2016
Target sample size	45
Recruitment status	Recruiting
Primary outcome (s)	Ability and confidence of the proband to communicate genetic results to at-risk relatives
Key secondary outcomes	Secondary outcomes will assess genetic knowledge, satisfaction with services, outcomes from genetic counselling and psychological adaptation to genetic information

Table 2: Certainty sub-scale of the PAGIS scale

1. I understand how I came to have hypertrophic cardiomyopathy
 2. I understand the health risks my relatives face because of hypertrophic cardiomyopathy
 3. I feel certain that I understand the meaning of having hypertrophic cardiomyopathy
 4. I understand the chances I have of passing hypertrophic cardiomyopathy along to my children
 5. I feel that I can explain to other people what having hypertrophic cardiomyopathy means
 6. I feel confused because I have been given different explanations of what having hypertrophic cardiomyopathy means
-

Abbreviations: PAGIS = Psychological Adaptation to Genetic Information Scale.

Table 3: Primary outcome measure converted to a primary outcome

Measures incorporated

1. Certainty sub scale from PAGIS (measuring confidence)
2. Adult first degree relatives informed of genetic risk (measuring ability)

Calculation examples

Example 1:

Certainty score from PAGIS sub scale = $18/36 = 0.5$

Relatives informed of risk = $3/6 = 0.5$

= $(0.5 + 0.5 = 1) / 2 = 0.5$

= 50%

Therefore this participant falls into the 'poor communication' category of the primary outcome

Example 2:

Certainty score from PAGIS sub scale = $30/36 = 0.83$

Relatives informed of risk = $7/8 = 0.88$

$(0.88 + 0.83) / 2 = 0.86$

= 86%

Therefore this participant falls into the 'fair communication' category of this primary outcome

Abbreviations: PAGIS = Psychological Adaptation to Genetic Information Scale.

What is my genetic result?

Test Result	The Impact for You	The Impact for Your Family
Pathogenic (page 18)	This result is considered to be the definite cause of your disease.	We can look for the same variant in family members (cascade genetic testing).
Likely (probably) pathogenic (page 18)	This result is considered to be important and with the available evidence is thought to be the cause of HCM.	We can look for the same variant in family members (cascade genetic testing).
Variant of unknown significance (VUS) (page 20)	Currently we do not know if this variant is the cause of HCM or not. More evidence is needed.	Continue with current clinical screening guidelines, no cascade genetic testing options available at this time.
Benign or likely benign (page 16)	This variant is not the cause of HCM.	Continue with current clinical screening guidelines, no cascade genetic testing options available at this time.
No variant identified (indeterminate) (page 15)	No HCM variants have been identified.	Continue with current clinical screening guidelines, no cascade genetic testing options available at this time.

FIGURE 3: Example page from communication aid: What is my genetic result?

254x190mm (72 x 72 DPI)

Clinical screening guidelines for family members

Family member's age	How often you should see a cardiologist
0 - 5 years	Optional
6 - 10 years	Every 3 - 5 years
11 - 20 years	Every 12 - 18 months
21 - 30 years	Every 2 - 3 years
31 or more years	Every 3 - 5 years

This only applies to first-degree relatives (i.e. parents, brother/sister and children) of someone with HCM. If anyone in the family is having any symptoms suggesting a heart problem, they should see a cardiologist.

Worksheet

My family summary

Sharing this booklet with family members is encouraged.

If you're a family member reading this booklet, hopefully you will find some details below that apply directly to you.

All first-degree relatives of someone with HCM are recommended to have clinical screening to check for signs of HCM. This includes children, brothers/sisters and parents.

Clinical screening involves: echocardiogram (ultrasound of the heart) electrocardiogram (or ECG, an electrical trace of the heart rhythm), and physical examination with a cardiologist.

First name	Relation	Age	Clinical Screening	Genetic testing possibilities

FIGURE 4: Example page from communication aid: Family-screening guidelines

Communicating Hypertrophic Cardiomyopathy (HCM) Genetic Test Results

INFORMATION FOR PARTICIPANTS

Introduction

You are invited to take part in a research study examining how we can best communicate genetic test results in hypertrophic cardiomyopathy (HCM). Genetic testing for genetic heart diseases like HCM has become increasingly complex and our method of explaining these results needs to evolve to meet these changing needs. Cardiac genetic counsellors coordinate the genetic testing process and they play a key role in ensuring the information you are receiving is clear and meaningful for you and your family. The objective of this study is to compare the effectiveness of an intervention aimed at improving the way we communicate genetic test result information with our current usual care. If you consent to the study, you will be randomly assigned to either the new communication intervention or to usual care.

Individuals with hypertrophic cardiomyopathy are eligible to participate in this study if they are the first in their family to have genetic testing. People aged 16 years or older are eligible to participate; however children younger than this are excluded.

The study is being conducted by Dr Jodie Ingles, Prof Christopher Semsarian, Ms Laura Yeates and Ms Charlotte Burns from the Molecular Cardiology Research Program, Centenary Institute and Royal Prince Alfred Hospital Sydney.

Study Procedures

If you agree to participate in this study, you will be asked to complete the participant consent form. You will then be randomly allocated to one of two groups, to receive your genetic test result. Two weeks after your genetic test result appointment, you will be asked to complete a survey (*either paper or online*), asking about your understanding of genetic testing for HCM. This survey will take between 10-20 minutes to complete.

In addition, the researchers would like to phone you at one, three and six month intervals to follow up with you after you receive your genetic result. These phone calls will take approximately 10 minutes and will be conducted at a time that suits you.

1 Researchers will have access to your medical record to obtain information relevant
2 to this study. Information about you may also be sought from the *Australian Genetic*
3 *Heart Disease Registry*, if you have enrolled (www.heartregistry.org.au).
4 Confidentiality of the survey responses will be paramount. Your name will be
5 replaced with a unique code and only Dr Jodie Ingles will have access to the true
6 identity of respondents.
7

8
9 No additional genetic testing will be carried out as part of this study.

10
11 Information collected about you will be securely stored.
12

13 **Benefits**

14
15 While we intend that this research study furthers medical knowledge and may
16 improve management of genetic heart diseases in the future, it may not be of direct
17 benefit to you.
18

19 **Voluntary Participation**

20
21 Participation in this study is entirely voluntary. You do not have to take part in it. If
22 you do take part, you can withdraw at any time without having to give a reason.
23 Whatever your decision, please be assured that it will not affect your medical
24 treatment or your relationship with the staff who are caring for you.
25

26 **Confidentiality**

27
28 All of the information collected from you for the study will be treated confidentially,
29 and only the researchers named above will have access to it. The study results may
30 be presented at a conference or in a scientific publication, but individual participants
31 will not be identifiable in such a presentation.
32

33
34 Any forms completed online, including the participant consent form and survey will
35 be extremely secure to maintain participant privacy.
36

37 **Further Information**

38
39 When you have read this information, one of the investigators is available to discuss
40 it with you further and answer any questions you may have. If you would like to
41 know more at any stage, please feel free to contact:
42

Communicating Hypertrophic Cardiomyopathy (HCM) Genetic Test Results

PARTICIPANT CONSENT FORM

I, [name]
 of [address]
 [email]

have read and understood the Information for Participants on the abovenamed research study
 and have discussed the study with

I have been made aware of the procedures involved in the study.

I understand that my participation in this study will allow the researchers to have access to my
 medical record, including information held by the Australian Genetic Heart Disease Registry (if
 I am enrolled), and I agree to this.

I freely choose to participate in this study and understand that I can withdraw at any time.

I also understand that the research study is strictly confidential.

I hereby agree to participate in this research study.

Reporting checklist for protocol of a clinical trial.

Based on the SPIRIT guidelines.

Instructions to authors

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to include the missing information. If you are certain that an item does not apply, please write "n/a" and provide a short explanation.

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the SPIRIT reporting guidelines, and cite them as:

Chan A-W, Tetzlaff JM, Altman DG, Laupacis A, Gøtzsche PC, Krleža-Jerić K, Hróbjartsson A, Mann H, Dickersin K, Berlin J, Doré C, Parulekar W, Summerskill W, Groves T, Schulz K, Sox H, Rockhold FW, Rennie D, Moher D. ABSTRACT

Introduction: Genetic testing for hypertrophic cardiomyopathy (HCM) in the era of genomics brings unique challenges for genetic counselling. The number of genes routinely included in an HCM gene panel has increased markedly, many with minimal if any robust evidence of gene-disease association. Subsequently there is a greater chance of uncertain genetic findings. The responsibility of communicating this information with at-risk relatives lies with the index case (proband). We have developed a communication aid to assist with the delivery of genetic results to the proband. We have previously shown the aid is feasible and acceptable, and have now developed a study protocol for a randomised controlled trial of a genetic counsellor-led intervention incorporating the communication aid.

Methods and Analysis: This is a prospective randomised controlled trial. We will investigate the impact of a genetic counsellor-led intervention to return proband gene results using a custom designed communication aid. We aim to improve knowledge and empowerment. The primary outcome of this trial is the ability and confidence of the proband to communicate genetic results to at-risk relatives. Secondary outcomes will assess genetic knowledge, satisfaction with services, outcomes from genetic counselling and psychological adaptation to genetic information.

Ethics and Dissemination: This study has been approved by and is in strict accordance with the Sydney Local Health District Ethics Review Committee (X16-0030; 22/01/2016; version 1). Results from this trial will be prepared as a manuscript and submitted to peer-reviewed journals for publication as well as submission for presentation at national and international meetings.

Registration Details: This trial is registered with the Australian New Zealand Clinical Trials Registry: ACTRN12617000706370

STRENGTHS AND LIMITATIONS

- This study will assess the effectiveness of a communication aid to improve the ability and confidence of patients with hypertrophic cardiomyopathy (HCM) to communicate genetic test results with their at-risk relatives.
- The results of this trial will inform genetic counselling practice for HCM genetic testing, as well as be broadly applicable for other inherited heart diseases.
- Limitations include the generalisability of our findings, which are true for a specialised multidisciplinary clinic where the intervention was performed but may not be representative of the broader HCM population undergoing genetic testing.
- As genomic technologies continue to evolve, uncertainty and complexity of genetic findings will likely increase over time.

INTRODUCTION

Background and rationale

Genetic testing in the era of genomics brings unique challenges for the genetic counselling of families. Hypertrophic cardiomyopathy (HCM) is a clinically heterogeneous inherited heart disease characterised by unexplained left ventricular hypertrophy in the absence of a loading condition such as hypertension.¹ With a prevalence of 1 in 200-500, it is one of the most common inherited heart diseases and clinical manifestations can range from asymptomatic through to heart failure or sudden cardiac death.² In the setting of HCM, genetic testing of the index case (proband) can provide invaluable information by allowing at-risk relatives the opportunity to undergo cascade genetic testing to look for the presence or absence of the family-specific variants.³ The first step is often the most challenging, requiring identification of a variant for which there is sufficient evidence of causation.

Genetic counselling is a critical aspect of the process, not just for genetic testing, but also for understanding inheritance risks, characterisation of the family history and information and emotional support.⁴ Within a clinical setting, pre- and post-test genetic counselling should include discussion of inheritance risks and clinical screening guidelines for at-risk relatives.⁵ This allows asymptomatic at-risk relatives to make proactive, informed decisions regarding their risk, including family planning decisions.

How a patient understands and communicates this genetic information to their at-risk relatives is critical to ensuring patients' get the most value out of genetic testing. This task of communication relies on the proband within the family. Current Australian practice and privacy laws dictate that in most cases the health care provider does not make contact with relatives to disclose risk information. Therefore, it follows that in order to communicate genetic results or risk information the proband must have adequate understanding of the

1
2 information they have received from their healthcare provider. Several studies indicate this
3
4 may be problematic, and some individuals may not retain or understand the information
5
6 presented to them.⁶
7
8
9

11 Existing knowledge

12
13 Currently literature estimates between 20-40% of relatives remain unaware of relevant
14
15 genetic information and do not act on information even when they have reportedly been
16
17 informed of their risk.⁷⁻⁹ Many factors have been identified which influence family
18
19 communication about genetic risk, including complicated family dynamics, guilt, anxiety
20
21 and gender, however are difficult to target as areas for improvement within the context of
22
23 one or two genetic counselling sessions.^{7 8 10 11} There are stages within the genetic
24
25 counselling process, where communication of genetic results and uptake of appropriate
26
27 screening may be influenced.
28
29
30

31
32
33
34 Our group and others have shown some of the barriers that can negatively impact on
35
36 family communication. In a qualitative study of HCM patients undergoing comprehensive
37
38 genetic testing, many patients reported uncertain results to be conveyed less amongst
39
40 families.¹² Further, these results are often misunderstood. For example, amongst this
41
42 cohort, probands with uncertain results perceived these results as falsely reassuring or
43
44 conversely suggests their disease is 'worse' or 'different'. This led to a misunderstanding
45
46 that their result was not heritable and therefore communication with relatives did not
47
48 occur.¹² Supporting these findings, the general genetics literature highlights that risk
49
50 perception and understanding of results though varied, can be poor, inaccurate and
51
52 incomplete.^{13 14}
53
54
55
56
57
58
59
60

1
2 There is evidence for the effectiveness of a genetic counsellor in addressing some of the
3 communication and knowledge barriers.¹⁵⁻¹⁷ One key area for intervention is during the
4 post-test genetic counselling session. Genetic and risk information can be difficult to
5 understand and explain clearly and as a consequence, the patient may not gain sufficient
6 knowledge and lack confidence to convey these key messages to at-risk relatives.¹²
7
8 Further, it is recognised that patients deliberate on the appropriate time to communicate
9 genetic information and make decisions regarding which relatives the information is
10 pertinent to, regardless of the recommendation of professionals.^{7 18 19} Few resources exist
11 which aim to facilitate effective communication to at-risk relatives. We therefore
12 hypothesise that improving knowledge of an HCM genetic diagnosis will have a positive
13 impact on communication to at-risk relatives, as well as genetic knowledge, satisfaction
14 with services, outcomes from genetic counselling and psychological adaptation to genetic
15 information.

34 **Utility of a communication aid**

35
36 When asked about family communication, most patients report families should
37 communicate risk amongst themselves with varying levels of support from their healthcare
38 providers.^{14 17 20} In addition, there is evidence for the effectiveness of genetic counselling
39 to assist with this process.^{15 16 20} Hodgson et al. published a randomised controlled trial
40 assessing the impact of a genetic counselling phone intervention on communication of
41 genetic information within families.²¹ They found no significant difference between the
42 intervention and control group when measuring contact with genetic services, though in
43 sub-analyses of the high-risk children group, the primary outcome was significantly
44 improved. Importantly, the primary outcome measure was contact with a genetic service,
45 which can be difficult to ascertain and may not be the most accurate measure of
46 effectiveness or a direct reflection of communication efforts.

1
2 Resources such as decision and communication aids, or family letters, may provide
3
4 additional support to this process, though more data is needed regarding efficacy.^{15 19 21 22}
5
6 Decision or communication aids are tools specifically designed to support patients with
7
8 decision making and unmet information needs. There is evidence for the effectiveness of
9
10 an aid with regard to improved knowledge and accuracy of risk perceptions.²³⁻²⁵ Further,
11
12 most health information is written which may not be the most effective health
13
14 communication method. Communication and decision aids provide a format to include
15
16 visual elements that may improve comprehension, recall and comfort with the information,
17
18 particularly when health literacy may be an issue.
19
20
21
22
23
24

25 **Need for a trial**

26
27 Overall, the literature highlights that probands require additional support to understand and
28
29 communicate genetic results. The rationale for this study is the critical gap in supporting
30
31 patients' comprehension and consequent communication of genetic risk to at-risk relatives.
32
33 Though genetic counsellors are specifically trained in delivering genetic information,
34
35 information needs of patients are not always met and communication amongst at-risk
36
37 relatives can be suboptimal. As genetic test results become increasingly complex, an
38
39 evidence-based approach to supporting patients with genetic knowledge and risk
40
41 communication should be explored.
42
43
44
45
46
47

48 **STUDY AIMS AND OUTCOMES**

49
50 The aim of this randomised controlled trial is to determine if a genetic counsellor-led
51
52 intervention using a communication aid for the delivery of HCM genetic test results
53
54 improves the ability and confidence of the proband to communicate genetic results to at-
55
56 risk relatives compared with current clinical practice.

1. The primary outcome is the ability and confidence of the proband to communicate genetic results to at-risk relatives, measured at 2 weeks post-intervention.
2. Secondary outcomes will assess genetic knowledge, satisfaction with services, patient reported outcome of genetic counselling and psychological adaptation to genetic information, measured at 2 weeks post-intervention.
3. As a longer-term outcome, we will systematically assess and document family communication as reported by the proband measured by phone calls at one, three and six monthly intervals. The researcher conducting these phone calls will not be blinded to the treatment arm of the participant. During these phone calls a series of questions regarding family communication and uptake of family screening will be asked of the proband. These phone calls will be conducted and analysed after collection of the primary and secondary outcomes data. This is to prevent interference with results because the phone calls themselves may serve as a family communication intervention. A phone script to be used as a guide for these phone calls is available in the supplementary material.

METHODS AND ANALYSIS

Trial design

This is a prospective randomised controlled trial. The protocol is reported in accordance with the SPIRIT statement, which provides recommendations for a minimum set of scientific, ethical and administrative elements that should be addressed within a clinical trial protocol.²⁶ All items from the World Health Organization Trial Registration Data Set are listed in Table 1. Consecutive HCM patients will be invited to participate when they are notified on the phone that their genetic result is ready to be returned. Once written consent is obtained they will be randomised to receive their genetic result via the intervention or control arm of the study (Figure 1).

Study setting

This trial will be carried out within a specialised multidisciplinary HCM clinic. This incorporates the expertise of specialist cardiologists and cardiac genetic counsellors.²⁷ Patients with HCM attending these clinics at Royal Prince Alfred Hospital will be invited to attend.

Eligibility criteria

HCM probands with a genetic result ready for return are eligible. HCM probands are defined as the first person in the family to undergo genetic testing for HCM. Probands include those with and without a family history of disease provided genetic testing has been ordered. Participants must be aged 16 years or older, with sufficient written English skills as nominated by the participant. Genetic testing is performed as part of a research study, or commercial laboratory as previously published.^{28 29} All identified variants are classified in the same manner, as per current clinical standards and guidelines.³⁰ Recruitment commenced in November 2017 and is expected to end in November 2018.

1
2 Participants will be invited to participate in the study during their routine pre clinic phone
3
4 call conducted as normal clinical process. Informed consent will be obtained by the cardiac
5
6 genetic counsellor present at the participants clinic consultation (supplementary material).
7
8
9

10 11 **Randomisation**

12
13 A randomised list was prepared using the Excel (Microsoft Office) "Random" function and
14
15 study participants who consent to the study are allocated the next number on the random
16
17 list. This number is linked to either control or intervention. A researcher not involved in the
18
19 study performs the randomisation.
20
21
22
23

24 25 **Sample size and power calculations**

26
27 Prior to commencement of the study, power calculations were performed using the results
28
29 from our published feasibility study.³¹ The primary outcome of this trial is the ability and
30
31 confidence of the proband to communicate genetic results to at-risk relatives. Data from
32
33 the feasibility study indicated 75% of participants communicated genetic results to at-risk
34
35 relatives. Assuming the control group communicates in 50% of cases, at a significance
36
37 level of 5% and 80% statistical power, a sample size of n=21 is required per group.
38
39
40
41
42

43 44 **Development of the custom communication aid**

45
46 We have developed a communication aid to assist with the delivery of genetic results to
47
48 the proband and support family communication. A pilot study demonstrating feasibility and
49
50 acceptability of this aid has been previously reported.³¹ In brief, development of the aid
51
52 involved review of the literature alongside multidisciplinary meetings. Development was a
53
54 multistep process and on the basis of meeting outcomes, literature review and empirical
55
56 evidence from the multidisciplinary team. The aid addresses:
57
58

- 59 1. Genetic test basic background information
- 60

- 1
 - 2

2. Possible outcomes of genetic testing
 3. Overview of the process involved in classification of a genetic variant
 4. Implications for at-risk relatives including family screening recommendations

Control arm

Those within the control arm of the study will receive their result via normal clinical practice. There are currently no evidence-based guidelines for return of comprehensive genetic test results within the multidisciplinary clinic setting. Normal clinical practice typically involves return of a genetic result either by the cardiologist or genetic counsellor. Return of the result is usually performed following clinical cardiology review, which is often the primary purpose of the consult. In the majority of cases a genetic counsellor is present.

Intervention arm

Those randomised to the intervention arm will be allocated a separate appointment time after clinical review with their cardiologist, where they will see the cardiac genetic counsellor who will return their genetic result using the communication aid.

The communication aid covers the process of genetic testing and risk from diagnosis of HCM through to the implications of a genetic result for at-risk relatives (Figure 2). There is a section in the aid under 'Results', which goes through the meaning of each category of genetic result. These include an indeterminate result (no variant identified), a variant of uncertain significance and a likely pathogenic/pathogenic result (Figure 3). The genetic counsellor returning the genetic result will mark the appropriate category of result, which applies to the patient in front of them. The genetic counsellor will return the genetic result, and then go through the communication aid, referencing the individual result and specific recommendations for the rest of the family. There will be an opportunity to ask questions,

1
2 and the genetic counsellor will write the specific recommendations for each family member
3
4 in the box provided at the end of the communication aid (Figure 4).
5
6
7

8 **Patient and Public Involvement**

9
10
11 Development of this research question and outcome measures were informed by clinical
12
13 experience of the authors in a specialised clinic setting, as well as published research
14
15 identifying gaps in communication with relatives. Specifically, there are known challenges
16
17 associated with understanding and subsequent communication of genetic information to
18
19 relatives. We have shown poor understanding, recall, and communication of genetic
20
21 results amongst HCM probands.^{7 12} Prior to implementation and development of this trial, a
22
23 pilot study involving patients was conducted, incorporating patient preference and needs
24
25 allowing development of both the communication aid and the study protocol.³¹ Results will
26
27 be disseminated to patients in the form of a research participant newsletter on completion
28
29 of the study. In addition, those randomised to the control arm will receive a copy of the
30
31 communication aid. Patients provided written consent to participate in the study, with an
32
33 understanding of the requirements of the study. These were not considered by the patients
34
35 or study team to be burdensome for the patients participating in the study.
36
37
38
39
40
41
42

43 **DATA COLLECTION AND OUTCOMES**

44
45 Both the primary and secondary outcomes will be measured at a single time point (2-
46
47 weeks post intervention) using a survey comprised of a number of previously published
48
49 and validated scales. A number of demographic questions will also be asked within the
50
51 survey. The survey will be available online via qualtrics (<https://www.qualtrics.com/>) with a
52
53 direct link sent to participants. For those who prefer a hard copy it will be posted with a
54
55 return envelope. The survey will be sent two weeks after return of genetic results.
56
57
58
59 Evidence regarding the most appropriate time between genetic result disclosure and family
60

1
2 communication is lacking. However, given the risk of arrhythmia and sudden death within
3
4 the inherited heart disease context, two weeks post result disclosure was considered by
5
6 the study team to be an appropriate time point to send the survey.²⁵ Return of the survey
7
8 is followed up on a fortnightly basis.
9

10 11 12 13 **Primary outcome** 14

15
16 The primary outcome of this trial is the ability and confidence of the proband to
17
18 communicate genetic results to at-risk relatives. This will be measured at a single time
19
20 point, administered two weeks after return of genetic results. Ability and confidence will be
21
22 assessed by two measures and then combined into a binary outcome. The certainty sub-
23
24 scale of the Psychological Adaptation to Genetic Information (PAGIS) scale will measure
25
26 confidence with genetic knowledge.³² This sub-scale measures the patients' perception
27
28 and confidence in their genetic knowledge and the items from this sub-scale are listed in
29
30 Table 2. Subsequent ability to pass this information on will be measured by the number of
31
32 at-risk relatives informed of genetic results by the proband. We will average the scores
33
34 from both measures to determine a final score. The calculations used to determine this
35
36 cut-off are illustrated in Table 3.
37
38
39
40
41
42

43
44 In summary, we will calculate the total PAGIS certainty sub-scale score (denominator of
45
46 36). This will be added to the total number of relatives informed over the total number of
47
48 relatives at risk. This number will then be converted to a percentage. The final score will be
49
50 converted to a binary outcome of fair versus poor ability and confidence to communicate
51
52 genetic results to at-risk relatives. A cut-off of $\geq 75\%$ will be used to indicate fair
53
54 communication, based on data indicating 20-40% of relatives are not informed of their
55
56 genetic risk. This outcome has been specifically designed for this study.
57
58
59
60

1
2 Factors that influence communication of genetic results to at-risk relatives are
3 multidimensional. For this reason, we chose this combination approach to more broadly
4 reflect the communication process. Many studies rely on single and linear measures of
5 communication such as contact by relatives with genetics departments or self reported
6 communication with at-risk relatives only. To overcome this, we aimed to incorporate a
7 multidimensional approach that included the probands confidence regarding their
8 knowledge of genetics alongside the action linked to this knowledge, being the
9 communication to relatives. This will aim to determine consistency between the probands
10 confidence with genetic information against their self-reported percentage of immediate
11 family members informed
12
13
14
15
16
17
18
19
20
21
22
23

24
25
26
27 The certainty sub-scale of the Psychological Adaptation to Genetic Information Scale
28 (PAGIS) will be used to measure confidence with genetic knowledge as described
29 above.³² Guided by grounded theory in patient perspectives of genetic counselling and the
30 Roy Adaptation to Genetic Information Model, the 26-item PAGIS scale allows for
31 evaluation of the efficacy of genetic counselling.^{32 33} The scale aims to incorporate the
32 multidimensional adaptation to genetic information and comprises of five domains which
33 include; a) non-intrusiveness, b) support c) self-worth, d) certainty and e) self-efficacy.³²
34

57
58
59
60

Evidence for the utility of this scale has been published and illustrates its potential use for
assessing genetic counselling interventions.³²

Secondary outcomes

The survey comprises three additional scales to assess primary and secondary outcomes, a number of questions regarding communication with relatives, as well as a number of demographic questions.

1
2 Genetic knowledge will be assessed using an amended version of the Breast Cancer
3
4 Genetic Counseling Knowledge Questionnaire (BGKQ).^{33 34} This scale was originally
5
6 developed to assess knowledge of information typically included in genetic counselling for
7
8 breast cancer. The original scale was a 27 item questionnaire including statements
9
10 regarding genetics such as '*50% (half) of your genetic information was passed down from*
11
12 *your mother*' and participants were asked if the statement was true or false. Items in the
13
14 original scale were empirically derived from detailed content analysis of breast cancer
15
16 genetic counselling sessions. The original scale demonstrated a high content validity with
17
18 cronbachs $\alpha = 0.92$, with demonstrated ability to discriminate between patients before and
19
20 after genetic counselling sessions.³⁴ We have amended questions to reflect the HCM
21
22 context and 10 items were included.
23
24
25
26
27
28

29 Satisfaction with services received will be assessed using the widely used Satisfaction with
30
31 Genetic Counseling Scale (SGCS).³⁵ The original questionnaire was designed to assess
32
33 three dimensions of patient satisfaction: instrumental, affective and procedural.^{33 35} This
34
35 survey will use an amended version of the 12 item short form of the survey.
36
37
38
39
40

41 The genetic counselling outcome scale (GCOS-24) will be used to assess patient reported
42
43 outcomes of genetic counselling.³⁶ The questionnaire was designed to be used pre and
44
45 post genetic counselling, though we have used it in the post counselling setting. The
46
47 authors of this scale used the construct of empowerment to summarise the patient derived
48
49 benefits from genetic counselling.
50
51
52
53
54

55 **Data management**

56
57 All data from the survey will be entered into Microsoft Excel. Patient identifiers will be
58
59 removed with study codes allocated. The primary researcher will be blinded to treatment
60

1
2 arm of the patient for analysis of the primary and secondary outcome data. A second
3
4 senior researcher and supervisor will oversee data storage and analysis. Data will be
5
6 stored in accordance with the Sydney Local Health District Ethics Review Committee and
7
8 Centenary Institute.
9

10 11 12 13 **Data analysis plan** 14

15
16 Data will be analysed using Prism (version 7.0) and SPSS (Version 23.0). We will compare
17
18 the primary outcome as a binary measure between the intervention and control group. We
19
20 will use chi-square analyses using $p < 0.05$ for statistical significance. For assessment of
21
22 secondary outcomes we will be guided by published scoring systems for the validated
23
24 scales to score genetics knowledge, satisfaction with services and genetic counselling
25
26 outcomes. Mean scores for each scale will be compared between the intervention and
27
28 control group and comparisons between the control and intervention group will be
29
30 analysed using unpaired t-tests for continuous data and chi-square analysis for categorical
31
32 data. Sub-group analysis will also be performed; specifically we will compare outcomes in
33
34 the study groups stratified by the gene result (i.e. causative, uncertain or indeterminate
35
36 results) and compare familial and non-familial HCM probands, which has been previously
37
38 shown to influence family communication practices.³⁷
39
40
41
42
43
44

45
46 As a longer-term outcome, we will systematically assess and document family
47
48 communication as reported by the proband measured by phone calls at one, three and six
49
50 monthly intervals. These phone calls will also measure uptake of family screening as
51
52 reported by the proband. This will be assessed separately to the primary and secondary
53
54 outcomes. We will compare outcomes between the study groups stratified by the gene
55
56 result (i.e. causative, uncertain or indeterminate results). In addition, we will compare
57
58
59
60

1
2 outcomes between study groups stratified by those with and without a family history of
3
4 HCM.
5
6
7

8 **ETHICS AND DISSEMINATION**

10 **Ethics**

11
12 All aspects of the study will be performed according to institutional human research ethics
13
14 committee approval. This study has been approved by and is in strict accordance with the
15
16 Sydney Local Health District Ethics Review Committee (X16-0030).
17
18
19
20
21

22 **Dissemination**

23
24 Results from this trial will be prepared as a manuscript and submitted to peer-reviewed
25
26 journals for publication. In addition, it will form part of the first authors' PhD thesis. Results
27
28 from the study will be submitted to international and national scientific sessions with the
29
30 aim of being presented. We will make a copy of the aid available to a wider genetic
31
32 audience for use in their clinical practice and study data will be available from the authors.
33
34
35 This will include development of an electronic form of the aid.

ACKNOWLEDGEMENTS AND FUNDING

CB is the recipient of an Australia Postgraduate Award (APA). CS is the recipient of a National Health and Medical Research Council (NHMRC) Practitioner Fellowship (#1059156). JI is the recipient of a National Heart Foundation of Australia Future Leader Fellowship (#100833).

We thank Yana Smagarinsky for her assistance with developing the communication aid and Katharine Morgan for graphic design of the communication aid.

AUTHOR STATEMENT

All authors contributed to the manuscript, specifically:

- (1) Substantial contributions to the conception or design of the work; or the acquisition, analysis, or interpretation of data for the work (CB, LY, CS, JI); AND
- (2) Drafting the work or revising it critically for important intellectual content (CB, LY, CS, JI); AND
- (3) Final approval of the version to be published (CB, LY, CS, JI); AND
- (4) Agreement to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved (CB, LY, CS, JI).

COMPETING INTERESTS

All authors declare they have no disclosures regarding competing interests.

Table 1: Trial Registration Data

Primary registry and trial identifying number	Australian New Zealand Clinical Trials Registry: ACTRN12617000706370
Date of registration in primary registry	17/05/2017
Secondary identifying numbers	NA
Source(s) of monetary or material support	National Heart Foundation of Australia
Primary sponsor	The University of Sydney
Secondary sponsor	NA
Contact for public queries	Dr Jodie Ingles j.ingles@centenary.org.au
Contact for scientific queries	Dr Jodie Ingles j.ingles@centenary.org.au
Public title	Use of an aid to improve communication of genetic risk information to families with hypertrophic cardiomyopathy (HCM)
Scientific title	Use of a custom designed aid to improve communication of genetic results in families with HCM
Countries of recruitment	Australia
Health condition (s) or problem (s) studied	HCM
Intervention	Use of a custom designed aid to communicate HCM genetic test results
Key inclusion and exclusion criteria	HCM probands with a genetic result ready for return Participants must be aged 18 years or older Sufficient written English skills as nominated by the participant
Study type	Prospective randomised controlled trial
Date of first enrolment	25/11/2016
Target sample size	45
Recruitment status	Recruiting
Primary outcome (s)	Ability and confidence of the proband to communicate genetic results to at-risk relatives
Key secondary outcomes	Secondary outcomes will assess genetic knowledge, satisfaction with services, outcomes from genetic counselling and psychological adaptation to genetic information

Table 2: Certainty sub-scale of the PAGIS scale

1. I understand how I came to have hypertrophic cardiomyopathy
 2. I understand the health risks my relatives face because of hypertrophic cardiomyopathy
 3. I feel certain that I understand the meaning of having hypertrophic cardiomyopathy
 4. I understand the chances I have of passing hypertrophic cardiomyopathy along to my children
 5. I feel that I can explain to other people what having hypertrophic cardiomyopathy means
 6. I feel confused because I have been given different explanations of what having hypertrophic cardiomyopathy means
-

Abbreviations: PAGIS = Psychological Adaptation to Genetic Information Scale.

Table 3: Primary outcome measure converted to a primary outcome

Measures incorporated

1. Certainty sub scale from PAGIS (measuring confidence)
2. Adult first degree relatives informed of genetic risk (measuring ability)

Calculation examples

Example 1:

Certainty score from PAGIS sub scale = $18/36 = 0.5$

Relatives informed of risk = $3/6 = 0.5$

= $(0.5 + 0.5 = 1) / 2 = 0.5$

= 50%

Therefore this participant falls into the 'poor communication' category of the primary outcome

Example 2:

Certainty score from PAGIS sub scale = $30/36 = 0.83$

Relatives informed of risk = $7/8 = 0.88$

$(0.88 + 0.83) / 2 = 0.86$

= 86%

Therefore this participant falls into the 'fair communication' category of this primary outcome

Abbreviations: PAGIS = Psychological Adaptation to Genetic Information Scale.

What is my genetic result?

Test Result	The Impact for You	The Impact for Your Family
Pathogenic (page 18)	This result is considered to be the definite cause of your disease.	We can look for the same variant in family members (cascade genetic testing).
Likely (probably) pathogenic (page 18)	This result is considered to be important and with the available evidence is thought to be the cause of HCM.	We can look for the same variant in family members (cascade genetic testing).
Variant of unknown significance (VUS) (page 20)	Currently we do not know if this variant is the cause of HCM or not. More evidence is needed.	Continue with current clinical screening guidelines, no cascade genetic testing options available at this time.
Benign or likely benign (page 16)	This variant is not the cause of HCM.	Continue with current clinical screening guidelines, no cascade genetic testing options available at this time.
No variant identified (indeterminate) (page 15)	No HCM variants have been identified.	Continue with current clinical screening guidelines, no cascade genetic testing options available at this time.

How certain are we that a variant is the cause of HCM?

My family summary

Sharing this booklet with family members is encouraged.

If you're a family member reading this booklet, hopefully you will find some details below that apply directly to you.

All first-degree relatives of someone with HCM are recommended to have clinical screening to check for signs of HCM. This includes children, brothers/sisters and parents.

Clinical screening involves: echocardiogram (ultrasound of the heart) electrocardiogram (or ECG, an electrical trace of the heart rhythm), and physical examination with a cardiologist.

First name	Relation	Age	Clinical Screening	Genetic testing possibilities

Clinical screening guidelines for family members

Family member's age	How often you should see a cardiologist
0 - 5 years	Optional
6 - 10 years	Every 3 - 5 years
11 - 20 years	Every 12 - 18 months
21 - 30 years	Every 2 - 3 years
31 or more years	Every 3 - 5 years

This only applies to first-degree relatives (i.e. parents, brother/sister and children) of someone with HCM. If anyone in the family is having any symptoms suggesting a heart problem, they should see a cardiologist.

Figure 4

349x225mm (300 x 300 DPI)

Communicating Hypertrophic Cardiomyopathy (HCM) Genetic Test Results

INFORMATION FOR PARTICIPANTS

Introduction

You are invited to take part in a research study examining how we can best communicate genetic test results in hypertrophic cardiomyopathy (HCM). Genetic testing for genetic heart diseases like HCM has become increasingly complex and our method of explaining these results needs to evolve to meet these changing needs. Cardiac genetic counsellors coordinate the genetic testing process and they play a key role in ensuring the information you are receiving is clear and meaningful for you and your family. The objective of this study is to compare the effectiveness of an intervention aimed at improving the way we communicate genetic test result information with our current usual care. If you consent to the study, you will be randomly assigned to either the new communication intervention or to usual care.

Individuals with hypertrophic cardiomyopathy are eligible to participate in this study if they are the first in their family to have genetic testing. People aged 16 years or older are eligible to participate; however children younger than this are excluded.

The study is being conducted by Dr Jodie Ingles, Prof Christopher Semsarian, Ms Laura Yeates and Ms Charlotte Burns from the Molecular Cardiology Research Program, Centenary Institute and Royal Prince Alfred Hospital Sydney.

Study Procedures

If you agree to participate in this study, you will be asked to complete the participant consent form. You will then be randomly allocated to one of two groups, to receive your genetic test result. Two weeks after your genetic test result appointment, you will be asked to complete a survey (*either paper or online*), asking about your understanding of genetic testing for HCM. This survey will take between 10-20 minutes to complete.

In addition, the researchers would like to phone you at one, three and six month intervals to follow up with you after you receive your genetic result. These phone calls will take approximately 10 minutes and will be conducted at a time that suits you.

1 Researchers will have access to your medical record to obtain information relevant
2 to this study. Information about you may also be sought from the *Australian Genetic*
3 *Heart Disease Registry*, if you have enrolled (www.heartregistry.org.au).
4 Confidentiality of the survey responses will be paramount. Your name will be
5 replaced with a unique code and only Dr Jodie Ingles will have access to the true
6 identity of respondents.
7

8
9 No additional genetic testing will be carried out as part of this study.

10
11 Information collected about you will be securely stored.
12

13 **Benefits**

14
15 While we intend that this research study furthers medical knowledge and may
16 improve management of genetic heart diseases in the future, it may not be of direct
17 benefit to you.
18

19 **Voluntary Participation**

20
21 Participation in this study is entirely voluntary. You do not have to take part in it. If
22 you do take part, you can withdraw at any time without having to give a reason.
23 Whatever your decision, please be assured that it will not affect your medical
24 treatment or your relationship with the staff who are caring for you.
25

26 **Confidentiality**

27
28 All of the information collected from you for the study will be treated confidentially,
29 and only the researchers named above will have access to it. The study results may
30 be presented at a conference or in a scientific publication, but individual participants
31 will not be identifiable in such a presentation.
32

33
34 Any forms completed online, including the participant consent form and survey will
35 be extremely secure to maintain participant privacy.
36

37 **Further Information**

38
39 When you have read this information, one of the investigators is available to discuss
40 it with you further and answer any questions you may have. If you would like to
41 know more at any stage, please feel free to contact:
42

Communicating Hypertrophic Cardiomyopathy (HCM) Genetic Test Results

PARTICIPANT CONSENT FORM

I, [name]
 of [address]
 [email]

have read and understood the Information for Participants on the abovenamed research study
 and have discussed the study with

I have been made aware of the procedures involved in the study.

I understand that my participation in this study will allow the researchers to have access to my medical record, including information held by the Australian Genetic Heart Disease Registry (if I am enrolled), and I agree to this.

I freely choose to participate in this study and understand that I can withdraw at any time.

I also understand that the research study is strictly confidential.

I hereby agree to participate in this research study.

NAME:

SIGNATURE:

DATE:

NAME OF WITNESS:

SIGNATURE OF WITNESS:

Hello, this is (Insert Name) from the Centenary Institute, may I please speak to (Participant name)?

I am phoning (as we discussed back in (insert month of genetic result return) to follow up with you after you received your genetic result as part of our research into communicating genetic results. This is your (one month, three month, six month) follow up phone call. I was hoping to get some additional information from you regarding your gene result. Do you have 10 minutes or so to do this now- or I can arrange a more appropriate time?

SECTION 1: 3-generation pedigree documented – Have this documented prior to phone call. Confirm during phone call.

SECTION 2

**Who in the family have you told about the following: (List names/details):
Your diagnosis of HCM?**

About your genetic result?

**Who in the family has had an echo/ecg/Cardiology review- Outcome?
(Assess against guidelines)?**

Who in the family has had genetic testing- Outcome?

Who in the family is awaiting an appointment- with whom?

SECTION 3:

Total number of first degree relatives informed of diagnosis =

Total number of first degree relatives informed of genetic test outcome=

Total number of first degree relatives who have had cardiology review=

Total number of first degree relatives who have had genetic review=

Total number of first degree relatives awaiting review=

Total number of first degree relatives with a positive clinical screen=

Total number of relatives with a negative clinical screen =

Total number of first degree relatives with a positive genetic result =

Total number of first degree relatives with a negative genetic result=

Total number of other relatives informed =

Reporting checklist for protocol of a clinical trial.

Based on the SPIRIT guidelines.

Instructions to authors

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to include the missing information. If you are certain that an item does not apply, please write "n/a" and provide a short explanation.

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the SPIRIT reporting guidelines, and cite them as:

Chan A-W, Tetzlaff JM, Altman DG, Laupacis A, Gøtzsche PC, Krleža-Jerić K, Hróbjartsson A, Mann H, Dickersin K, Berlin J, Doré C, Parulekar W, Summerskill W, Groves T, Schulz K, Sox H, Rockhold FW, Rennie D, Moher D. ABSTRACT

Introduction: Genetic testing for hypertrophic cardiomyopathy (HCM) in the era of genomics brings unique challenges for genetic counselling. The number of genes routinely included in an HCM gene panel has increased markedly, many with minimal if any robust evidence of gene-disease association. Subsequently there is a greater chance of uncertain genetic findings. The responsibility of communicating this information with at-risk relatives lies with the index case (proband). We have developed a communication aid to assist with the delivery of genetic results to the proband. We have previously shown the aid is feasible and acceptable, and have now developed a study protocol for a randomised controlled trial of a genetic counsellor-led intervention incorporating the communication aid.

Methods and Analysis: This is a prospective randomised controlled trial. We will investigate the impact of a genetic counsellor-led intervention to return proband genetic results using a custom designed communication aid. We aim to improve knowledge and empowerment. The primary outcome of this trial is the ability and confidence of the proband to communicate genetic results to at-risk relatives. Secondary outcomes will assess genetic knowledge, satisfaction with services, outcomes from genetic counselling and psychological adaptation to genetic information.

Ethics and Dissemination: This study has been approved by and is in strict accordance with the Sydney Local Health District Ethics Review Committee (X16-0030; 22/01/2016; version 1). Results from this trial will be prepared as a manuscript and submitted to peer-reviewed journals for publication as well as submission for presentation at national and international meetings.

Registration Details: This trial is registered with the Australian New Zealand Clinical Trials Registry: ACTRN12617000706370

STRENGTHS AND LIMITATIONS

- This study will assess the effectiveness of a communication aid to improve the ability and confidence of patients with hypertrophic cardiomyopathy (HCM) to communicate genetic test results with their at-risk relatives.
- The results of this trial will inform genetic counselling practice for HCM genetic testing, as well as be broadly applicable for other inherited heart diseases.
- Limitations include the generalisability of our findings, which are true for a specialised multidisciplinary clinic where the intervention was performed but may not be representative of the broader HCM population undergoing genetic testing.
- As genomic technologies continue to evolve, uncertainty and complexity of genetic findings will likely increase over time.

INTRODUCTION

Background and rationale

Genetic testing in the era of genomics brings unique challenges for the genetic counselling of families. Hypertrophic cardiomyopathy (HCM) is a clinically heterogeneous inherited heart disease characterised by unexplained left ventricular hypertrophy in the absence of a loading condition such as hypertension.¹ With a prevalence of 1 in 200-500, it is one of the most common inherited heart diseases and clinical manifestations can range from asymptomatic through to heart failure or sudden cardiac death.² In the setting of HCM, genetic testing of the index case (proband) can provide invaluable information by allowing at-risk relatives the opportunity to undergo cascade genetic testing to look for the presence or absence of the family-specific variants.³ The first step is often the most challenging, requiring identification of a variant for which there is sufficient evidence of causation.

Genetic counselling is a critical aspect of the process, not just for genetic testing, but also for understanding inheritance risks, characterisation of the family history and information and emotional support.⁴ Within a clinical setting, pre- and post-test genetic counselling should include discussion of inheritance risks and clinical screening guidelines for at-risk relatives.⁵ This allows asymptomatic at-risk relatives to make proactive, informed decisions regarding their risk, including family planning decisions.

How a patient understands and communicates this genetic information to their at-risk relatives is critical to ensuring patients' get the most value out of genetic testing. This task of communication relies on the proband within the family. Current Australian practice and privacy laws dictate that in most cases the health care provider does not make contact with relatives to disclose risk information. Therefore, it follows that in order to communicate genetic results or risk information the proband must have adequate understanding of the

1
2 information they have received from their healthcare provider. Several studies indicate this
3
4 may be problematic, and some individuals may not retain or understand the information
5
6 presented to them.⁶
7
8
9

10 11 **Existing knowledge**

12
13 Currently literature estimates between 20-40% of relatives remain unaware of relevant
14
15 genetic information and do not act on information even when they have reportedly been
16
17 informed of their risk.⁷⁻⁹ Many factors have been identified which influence family
18
19 communication about genetic risk, including complicated family dynamics, guilt, anxiety
20
21 and gender, however these factors are difficult to target as areas for improvement within
22
23 the context of one or two genetic counselling sessions.^{7 8 10 11} There are stages within the
24
25 genetic counselling process, where communication of genetic results and uptake of
26
27 appropriate screening may be influenced.
28
29
30
31
32
33

34 Our group and others have shown some of the barriers that can negatively impact on
35
36 family communication. In a qualitative study of HCM patients undergoing comprehensive
37
38 genetic testing, many patients reported uncertain results to be conveyed less amongst
39
40 families.¹² Further, these results are often misunderstood. For example, amongst this
41
42 cohort, probands with uncertain results perceived these results as falsely reassuring or
43
44 conversely suggests their disease is 'worse' or 'different'. This led to a misunderstanding
45
46 that their result was not heritable and therefore communication with relatives did not
47
48 occur.¹² Supporting these findings, the general genetics literature highlights that risk
49
50 perception and understanding of results though varied, can be poor, inaccurate and
51
52 incomplete.^{13 14}
53
54
55
56
57
58
59
60

1
2 There is evidence for the effectiveness of a genetic counsellor in addressing some of the
3 communication and knowledge barriers.¹⁵⁻¹⁷ One key area for intervention is during the
4 post-test genetic counselling session. Genetic and risk information can be difficult to
5 understand and explain clearly and as a consequence, the patient may not gain sufficient
6 knowledge and lack confidence to convey these key messages to at-risk relatives.¹²
7
8 Further, it is recognised that patients deliberate on the appropriate time to communicate
9 genetic information and make decisions regarding which relatives the information is
10 pertinent to, regardless of the recommendation of professionals.^{7 18 19} Few resources exist
11 which aim to facilitate effective communication to at-risk relatives. We therefore
12 hypothesise that improving knowledge of an HCM genetic diagnosis will have a positive
13 impact on communication to at-risk relatives, as well as genetic knowledge, satisfaction
14 with services, outcomes from genetic counselling and psychological adaptation to genetic
15 information.

34 **Utility of a communication aid**

35
36 When asked about family communication, most patients report families should
37 communicate risk amongst themselves with varying levels of support from their healthcare
38 providers.^{14 17 20} In addition, there is evidence for the effectiveness of genetic counselling
39 to assist with this process.^{15 16 20} Hodgson et al. published a randomised controlled trial
40 assessing the impact of a genetic counselling phone intervention on communication of
41 genetic information within families.²¹ They found no significant difference between the
42 intervention and control group when measuring contact with genetic services, though in
43 sub-analyses of the high-risk children group, the primary outcome was significantly
44 improved. Importantly, the primary outcome measure was contact with a genetic service,
45 which can be difficult to ascertain and may not be the most accurate measure of
46 effectiveness or a direct reflection of communication efforts.

1
2 Resources such as decision and communication aids, or family letters, may provide
3
4 additional support to this process, though more data is needed regarding efficacy.^{15 19 21 22}
5
6 Decision or communication aids are tools specifically designed to support patients with
7
8 decision making and unmet information needs. There is evidence for the effectiveness of
9
10 an aid with regard to improved knowledge and accuracy of risk perceptions.²³⁻²⁵ Further,
11
12 most health information is provided in a written format, which may not be the most
13
14 effective health communication method. Communication and decision aids provide a
15
16 format to include visual elements that may improve comprehension, recall and comfort
17
18 with the information, particularly when health literacy may be an issue.
19
20
21
22
23
24

25 **Need for a trial**

26
27 Overall, the literature highlights that probands require additional support to understand and
28
29 communicate genetic results. The rationale for this study is the critical gap in supporting
30
31 patients' comprehension and consequent communication of genetic risk to at-risk relatives.
32
33 Though genetic counsellors are specifically trained in delivering genetic information,
34
35 information needs of patients are not always met and communication amongst at-risk
36
37 relatives can be suboptimal. As genetic test results become increasingly complex, an
38
39 evidence-based approach to supporting patients with genetic knowledge and risk
40
41 communication should be explored.
42
43
44
45
46
47

48 **STUDY AIMS AND OUTCOMES**

49
50 The aim of this randomised controlled trial is to determine if a genetic counsellor-led
51
52 intervention using a communication aid for the delivery of HCM genetic test results
53
54 improves the ability and confidence of the proband to communicate genetic results to at-
55
56 risk relatives compared with current clinical practice.

1. The primary outcome is the ability and confidence of the proband to communicate genetic results to at-risk relatives, measured at 2 weeks post-intervention.
2. Secondary outcomes will assess genetic knowledge, satisfaction with services, patient reported outcome of genetic counselling and psychological adaptation to genetic information, measured at 2 weeks post-intervention.
3. As a longer-term outcome, we will systematically assess and document family communication as reported by the proband measured by phone calls at one, three and six monthly intervals. The researcher conducting these phone calls will not be blinded to the treatment arm of the participant. During these phone calls a series of questions regarding family communication and uptake of family screening will be asked of the proband. These phone calls will be conducted and analysed after collection of the primary and secondary outcomes data. This is to prevent interference with results because the phone calls themselves may serve as a family communication intervention. A phone script to be used as a guide for these phone calls is available in the supplementary material.

METHODS AND ANALYSIS

Trial design

This is a prospective randomised controlled trial. The protocol is reported in accordance with the SPIRIT statement, which provides recommendations for a minimum set of scientific, ethical and administrative elements that should be addressed within a clinical trial protocol.²⁶ All items from the World Health Organization Trial Registration Data Set are listed in Table 1. Consecutive HCM patients will be invited to participate when they are notified on the phone that their genetic result is ready to be returned. Once written consent is obtained they will be randomised to receive their genetic result via the intervention or control arm of the study (Figure 1).

Study setting

This trial will be carried out within a specialised multidisciplinary HCM clinic. This incorporates the expertise of specialist cardiologists and cardiac genetic counsellors.²⁷ Patients with HCM attending these clinics at Royal Prince Alfred Hospital will be invited to attend.

Eligibility criteria

HCM probands with a genetic result ready for return are eligible. HCM probands are defined as the first person in the family to undergo genetic testing for HCM. Probands include those with and without a family history of disease provided genetic testing has been ordered. Participants must be aged 16 years or older, with sufficient written English skills as nominated by the participant. Genetic testing is performed as part of a research study, or commercial laboratory as previously published.^{28 29} All identified variants are classified in the same manner, as per current clinical standards and guidelines.³⁰ Recruitment commenced in November 2017 and is expected to end in November 2018.

1
2 Participants will be invited to participate in the study during their routine pre clinic phone
3
4 call conducted as normal clinical process. Informed consent will be obtained by the cardiac
5
6 genetic counsellor present at the participants clinic consultation (supplementary material).
7
8
9

10 11 **Randomisation**

12
13 A randomised list was prepared using the Excel (Microsoft Office) "Random" function and
14
15 study participants who consent to the study are allocated the next number on the random
16
17 list. This number is linked to either control or intervention. A researcher not involved in the
18
19 study performs the randomisation.
20
21
22
23

24 25 **Sample size and power calculations**

26
27 Prior to commencement of the study, power calculations were performed using the results
28
29 from our published feasibility study.³¹ The primary outcome of this trial is the ability and
30
31 confidence of the proband to communicate genetic results to at-risk relatives. Data from
32
33 the feasibility study indicated 75% of participants communicated genetic results to at-risk
34
35 relatives. Assuming the control group communicates in 50% of cases, at a significance
36
37 level of 5% and 80% statistical power, a sample size of n=21 is required per group.
38
39
40
41
42

43 44 **Development of the custom communication aid**

45
46 We have developed a communication aid to assist with the delivery of genetic results to
47
48 the proband and support family communication. A pilot study demonstrating feasibility and
49
50 acceptability of this aid has been previously reported.³¹ In brief, development of the aid
51
52 involved review of the literature alongside multidisciplinary meetings. Development was a
53
54 multistep process and on the basis of meeting outcomes, literature review and empirical
55
56 evidence from the multidisciplinary team. The aid addresses:
57
58

- 59 1. Genetic test basic background information

2. Possible outcomes of genetic testing
 3. Overview of the process involved in classification of a genetic variant
 4. Implications for at-risk relatives including family screening recommendations

Control arm

Those within the control arm of the study will receive their result via normal clinical practice. There are currently no evidence-based guidelines for return of comprehensive genetic test results within the multidisciplinary clinic setting. Normal clinical practice typically involves return of a genetic result either by the cardiologist or genetic counsellor. Return of the result is usually performed following clinical cardiology review, which is often the primary purpose of the consult. In the majority of cases a genetic counsellor is present.

Intervention arm

Those randomised to the intervention arm will be allocated a separate appointment time after clinical review with their cardiologist, where they will see the cardiac genetic counsellor who will return their genetic result using the communication aid.

The communication aid covers the process of genetic testing and risk from diagnosis of HCM through to the implications of a genetic result for at-risk relatives (Figure 2). There is a section in the aid under 'Results', which goes through the meaning of each category of genetic result. These include an indeterminate result (no variant identified), a variant of uncertain significance and a likely pathogenic/pathogenic result (Figure 3). The genetic counsellor returning the genetic result will mark the appropriate category of result, which applies to the patient in front of them. The genetic counsellor will return the genetic result, and then go through the communication aid, referencing the individual result and specific recommendations for the rest of the family. There will be an opportunity to ask questions,

1
2 and the genetic counsellor will write the specific recommendations for each family member
3
4 in the box provided at the end of the communication aid (Figure 4).
5
6
7

8 **Patient and Public Involvement**

9
10
11 Development of this research question and outcome measures were informed by clinical
12
13 experience of the authors in a specialised clinic setting, as well as published research
14
15 identifying gaps in communication with relatives. Specifically, there are known challenges
16
17 associated with understanding and subsequent communication of genetic information to
18
19 relatives. We have shown poor understanding, recall, and communication of genetic
20
21 results amongst HCM probands.^{7 12} Prior to implementation and development of this trial, a
22
23 pilot study involving patients was conducted, incorporating patient preference and needs
24
25 allowing development of both the communication aid and the study protocol.³¹ Results will
26
27 be disseminated to patients in the form of a research participant newsletter on completion
28
29 of the study. In addition, those randomised to the control arm will receive a copy of the
30
31 communication aid. Patients provided written consent to participate in the study, with an
32
33 understanding of the requirements of the study. These were not considered by the patients
34
35 or study team to be burdensome for the patients participating in the study.
36
37
38
39
40
41
42

43 **DATA COLLECTION AND OUTCOMES**

44
45 Both the primary and secondary outcomes will be measured at a single time point (2-
46
47 weeks post intervention) using a survey comprised of a number of previously published
48
49 and validated scales. A number of demographic questions will also be asked within the
50
51 survey. The survey will be available online via qualtrics (<https://www.qualtrics.com/>) with a
52
53 direct link sent to participants. For those who prefer a hard copy it will be posted with a
54
55 return envelope. The survey will be sent two weeks after return of genetic results.
56
57
58
59 Evidence regarding the most appropriate time between genetic result disclosure and family
60

1
2 communication is lacking. However, given the risk of arrhythmia and sudden death within
3
4 the inherited heart disease context, two weeks post result disclosure was considered by
5
6 the study team to be an appropriate time point to send the survey.²⁵ Return of the survey
7
8 is followed up on a fortnightly basis.
9

10 11 12 13 **Primary outcome** 14

15
16 The primary outcome of this trial is the ability and confidence of the proband to
17
18 communicate genetic results to at-risk relatives. This will be measured at a single time
19
20 point, administered two weeks after return of genetic results. Ability and confidence will be
21
22 assessed by two measures and then combined into a binary outcome. The certainty sub-
23
24 scale of the Psychological Adaptation to Genetic Information (PAGIS) scale will measure
25
26 confidence with genetic knowledge.³² This sub-scale measures the patients' perception
27
28 and confidence in their genetic knowledge and the items from this sub-scale are listed in
29
30 Table 2. Subsequent ability to pass this information on will be measured by the number of
31
32 at-risk relatives informed of genetic results by the proband. We will average the scores
33
34 from both measures to determine a final score. The calculations used to determine this
35
36 cut-off are illustrated in Table 3.
37
38
39
40
41
42

43
44 In summary, we will calculate the total PAGIS certainty sub-scale score (denominator of
45
46 36). This will be added to the total number of relatives informed over the total number of
47
48 relatives at risk. This number will then be converted to a percentage. The final score will be
49
50 converted to a binary outcome of fair versus poor ability and confidence to communicate
51
52 genetic results to at-risk relatives. A cut-off of $\geq 75\%$ will be used to indicate fair
53
54 communication, based on data indicating 20-40% of relatives are not informed of their
55
56 genetic risk. This outcome has been specifically designed for this study.
57
58
59
60

1
2 Factors that influence communication of genetic results to at-risk relatives are
3 multidimensional. For this reason, we chose this combination approach to more broadly
4 reflect the communication process. Many studies rely on single and linear measures of
5 communication such as contact by relatives with genetics departments or self reported
6 communication with at-risk relatives only. To overcome this, we aimed to incorporate a
7 multidimensional approach that included the probands confidence regarding their
8 knowledge of genetics alongside the action linked to this knowledge, being the
9 communication to relatives. This will aim to determine consistency between the probands
10 confidence with genetic information against their self-reported percentage of immediate
11 family members informed

23

24
25
26
27 The certainty sub-scale of the Psychological Adaptation to Genetic Information Scale
28 (PAGIS) will be used to measure confidence with genetic knowledge as described
29 above.³² Guided by grounded theory in patient perspectives of genetic counselling and the
30 Roy Adaptation to Genetic Information Model, the 26-item PAGIS scale allows for
31 evaluation of the efficacy of genetic counselling.^{32 33} The scale aims to incorporate the
32 multidimensional adaptation to genetic information and comprises of five domains which
33 include; a) non-intrusiveness, b) support c) self-worth, d) certainty and e) self-efficacy.³²

Secondary outcomes

The survey comprises three additional scales to assess primary and secondary outcomes, a number of questions regarding communication with relatives, as well as a number of demographic questions.

1
2 Genetic knowledge will be assessed using an amended version of the Breast Cancer
3
4 Genetic Counseling Knowledge Questionnaire (BGKQ).^{33 34} This scale was originally
5
6 developed to assess knowledge of information typically included in genetic counselling for
7
8 breast cancer. The original scale was a 27 item questionnaire including statements
9
10 regarding genetics such as '*50% (half) of your genetic information was passed down from*
11
12 *your mother*' and participants were asked if the statement was true or false. Items in the
13
14 original scale were empirically derived from detailed content analysis of breast cancer
15
16 genetic counselling sessions. The original scale demonstrated a high content validity with
17
18 cronbachs $\alpha = 0.92$, with demonstrated ability to discriminate between patients before and
19
20 after genetic counselling sessions.³⁴ We have amended questions to reflect the HCM
21
22 context and 10 items were included.
23
24
25
26
27
28

29 Satisfaction with services received will be assessed using the widely used Satisfaction with
30
31 Genetic Counseling Scale (SGCS).³⁵ The original questionnaire was designed to assess
32
33 three dimensions of patient satisfaction: instrumental, affective and procedural.^{33 35} This
34
35 survey will use an amended version of the 12 item short form of the survey.
36
37
38
39
40

41 The genetic counselling outcome scale (GCOS-24) will be used to assess patient reported
42
43 outcomes of genetic counselling.³⁶ The questionnaire was designed to be used pre and
44
45 post genetic counselling, though we have used it in the post counselling setting. The
46
47 authors of this scale used the construct of empowerment to summarise the patient derived
48
49 benefits from genetic counselling.
50
51
52
53
54

55 **Data management**

56
57 All data from the survey will be entered into Microsoft Excel. Patient identifiers will be
58
59 removed with study codes allocated. The primary researcher will be blinded to treatment
60

1
2 arm of the patient for analysis of the primary and secondary outcome data. A second
3
4 senior researcher and supervisor will oversee data storage and analysis. Data will be
5
6 stored in accordance with the Sydney Local Health District Ethics Review Committee and
7
8 Centenary Institute.
9

10 11 12 13 **Data analysis plan** 14

15
16 Data will be analysed using Prism (version 7.0) and SPSS (Version 23.0). We will compare
17
18 the primary outcome as a binary measure between the intervention and control group. We
19
20 will use chi-square analyses using $p < 0.05$ for statistical significance. For assessment of
21
22 secondary outcomes we will be guided by published scoring systems for the validated
23
24 scales to score genetics knowledge, satisfaction with services and genetic counselling
25
26 outcomes. Mean scores for each scale will be compared between the intervention and
27
28 control group and comparisons between the control and intervention group will be
29
30 analysed using unpaired t-tests for continuous data and chi-square analysis for categorical
31
32 data. Sub-group analysis will also be performed; specifically we will compare outcomes in
33
34 the study groups stratified by the genetic result (i.e. causative, uncertain or indeterminate
35
36 results) and compare familial and non-familial HCM probands, which has been previously
37
38 shown to influence family communication practices.³⁷
39
40
41
42
43
44

45
46 As a longer-term outcome, we will systematically assess and document family
47
48 communication as reported by the proband measured by phone calls at one, three and six
49
50 monthly intervals. These phone calls will also measure uptake of family screening as
51
52 reported by the proband. This will be assessed separately to the primary and secondary
53
54 outcomes. We will compare outcomes between the study groups stratified by the genetic
55
56 result (i.e. causative, uncertain or indeterminate results). In addition, we will compare
57
58
59
60

1
2 outcomes between study groups stratified by those with and without a family history of
3
4 HCM.
5
6
7

8 **ETHICS AND DISSEMINATION**

10 **Ethics**

11
12 All aspects of the study will be performed according to institutional human research ethics
13
14 committee approval. This study has been approved by and is in strict accordance with the
15
16 Sydney Local Health District Ethics Review Committee (X16-0030).
17
18
19
20
21

22 **Dissemination**

23
24 Results from this trial will be prepared as a manuscript and submitted to peer-reviewed
25
26 journals for publication. In addition, it will form part of the first authors' PhD thesis. Results
27
28 from the study will be submitted to international and national scientific sessions with the
29
30 aim of being presented. We will make a copy of the aid available to a wider genetic
31
32 audience for use in their clinical practice and study data will be available from the authors.
33
34
35 This will include development of an electronic form of the aid.

ACKNOWLEDGEMENTS AND FUNDING

CB is the recipient of an Australia Postgraduate Award (APA). CS is the recipient of a National Health and Medical Research Council (NHMRC) Practitioner Fellowship (#1059156). JI is the recipient of a National Heart Foundation of Australia Future Leader Fellowship (#100833).

We thank Yana Smagarinsky for her assistance with developing the communication aid and Katharine Morgan for graphic design of the communication aid.

AUTHOR STATEMENT

All authors contributed to the manuscript, specifically:

- (1) Substantial contributions to the conception or design of the work; or the acquisition, analysis, or interpretation of data for the work (CB, LY, CS, JI); AND
- (2) Drafting the work or revising it critically for important intellectual content (CB, LY, CS, JI); AND
- (3) Final approval of the version to be published (CB, LY, CS, JI); AND
- (4) Agreement to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved (CB, LY, CS, JI).

COMPETING INTERESTS

All authors declare they have no disclosures regarding competing interests.

Table 1: Trial Registration Data

Primary registry and trial identifying number	Australian New Zealand Clinical Trials Registry: ACTRN12617000706370
Date of registration in primary registry	17/05/2017
Secondary identifying numbers	NA
Source(s) of monetary or material support	National Heart Foundation of Australia
Primary sponsor	The University of Sydney
Secondary sponsor	NA
Contact for public queries	Dr Jodie Ingles j.ingles@centenary.org.au
Contact for scientific queries	Dr Jodie Ingles j.ingles@centenary.org.au
Public title	Use of an aid to improve communication of genetic risk information to families with hypertrophic cardiomyopathy (HCM)
Scientific title	Use of a custom designed aid to improve communication of genetic results in families with HCM
Countries of recruitment	Australia
Health condition (s) or problem (s) studied	HCM
Intervention	Use of a custom designed aid to communicate HCM genetic test results
Key inclusion and exclusion criteria	HCM probands with a genetic result ready for return Participants must be aged 18 years or older Sufficient written English skills as nominated by the participant
Study type	Prospective randomised controlled trial
Date of first enrolment	25/11/2016
Target sample size	45
Recruitment status	Recruiting
Primary outcome (s)	Ability and confidence of the proband to communicate genetic results to at-risk relatives
Key secondary outcomes	Secondary outcomes will assess genetic knowledge, satisfaction with services, outcomes from genetic counselling and psychological adaptation to genetic information

Table 2: Certainty sub-scale of the PAGIS scale

1. I understand how I came to have hypertrophic cardiomyopathy
 2. I understand the health risks my relatives face because of hypertrophic cardiomyopathy
 3. I feel certain that I understand the meaning of having hypertrophic cardiomyopathy
 4. I understand the chances I have of passing hypertrophic cardiomyopathy along to my children
 5. I feel that I can explain to other people what having hypertrophic cardiomyopathy means
 6. I feel confused because I have been given different explanations of what having hypertrophic cardiomyopathy means
-

Abbreviations: PAGIS = Psychological Adaptation to Genetic Information Scale.

Table 3: Primary outcome measure converted to a primary outcome

Measures incorporated

1. Certainty sub scale from PAGIS (measuring confidence)
2. Adult first degree relatives informed of genetic risk (measuring ability)

Calculation examples

Example 1:

Certainty score from PAGIS sub scale = $18/36 = 0.5$

Relatives informed of risk = $3/6 = 0.5$

= $(0.5 + 0.5 = 1) / 2 = 0.5$

= 50%

Therefore this participant falls into the 'poor communication' category of the primary outcome

Example 2:

Certainty score from PAGIS sub scale = $30/36 = 0.83$

Relatives informed of risk = $7/8 = 0.88$

$(0.88 + 0.83) / 2 = 0.86$

= 86%

Therefore this participant falls into the 'fair communication' category of this primary outcome

Abbreviations: PAGIS = Psychological Adaptation to Genetic Information Scale.

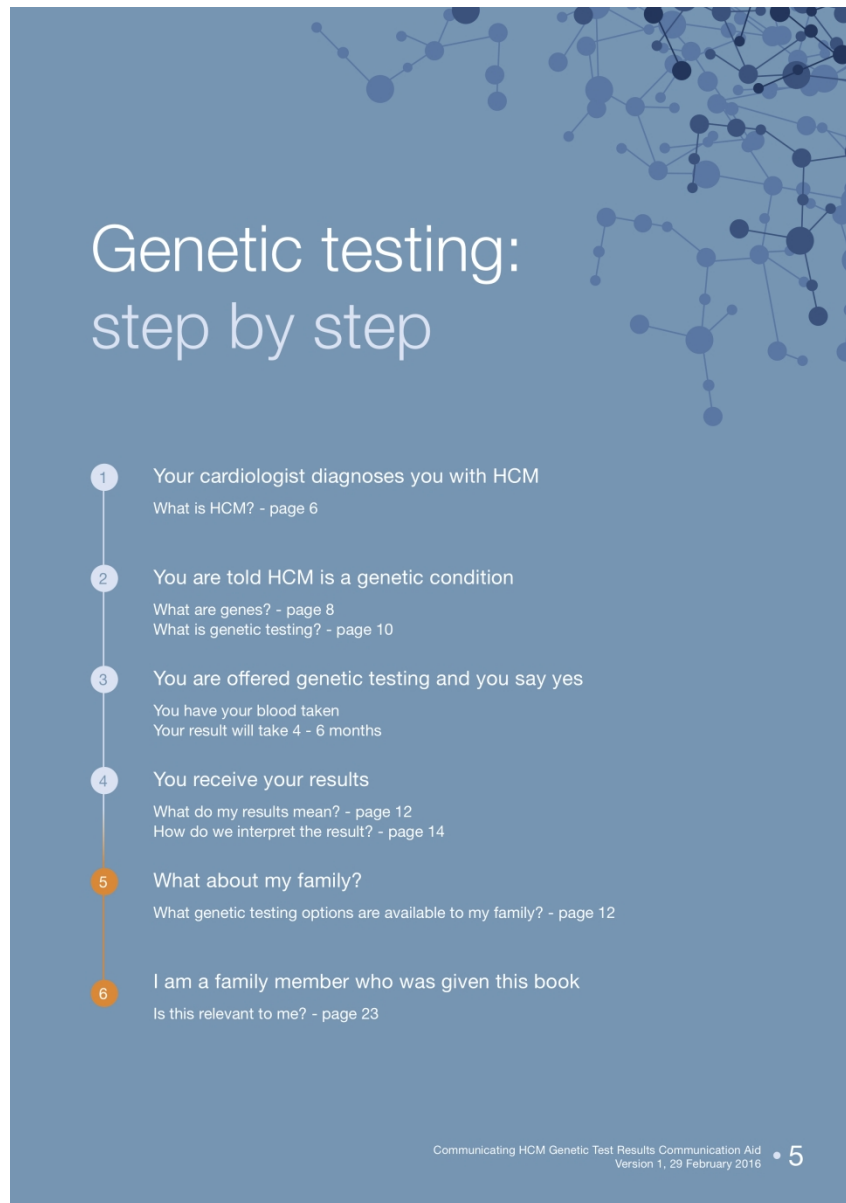

Figure 2

209x296mm (300 x 300 DPI)

What is my genetic result?

Test Result	The Impact for You	The Impact for Your Family
Pathogenic (page 18)	This result is considered to be the definite cause of your disease.	We can look for the same variant in family members (cascade genetic testing).
Likely (probably) pathogenic (page 18)	This result is considered to be important and with the available evidence is thought to be the cause of HCM.	We can look for the same variant in family members (cascade genetic testing).
Variant of unknown significance (VUS) (page 20)	Currently we do not know if this variant is the cause of HCM or not. More evidence is needed.	Continue with current clinical screening guidelines, no cascade genetic testing options available at this time.
Benign or likely benign (page 16)	This variant is not the cause of HCM.	Continue with current clinical screening guidelines, no cascade genetic testing options available at this time.
No variant identified (indeterminate) (page 15)	No HCM variants have been identified.	Continue with current clinical screening guidelines, no cascade genetic testing options available at this time.

How certain are we that a variant is the cause of HCM?

My family summary

Sharing this booklet with family members is encouraged.

If you're a family member reading this booklet, hopefully you will find some details below that apply directly to you.

All first-degree relatives of someone with HCM are recommended to have clinical screening to check for signs of HCM. This includes children, brothers/sisters and parents.

Clinical screening involves: echocardiogram (ultrasound of the heart) electrocardiogram (or ECG, an electrical trace of the heart rhythm), and physical examination with a cardiologist.

First name	Relation	Age	Clinical Screening	Genetic testing possibilities

Clinical screening guidelines for family members

Family member's age	How often you should see a cardiologist
0 - 5 years	Optional
6 - 10 years	Every 3 - 5 years
11 - 20 years	Every 12 - 18 months
21 - 30 years	Every 2 - 3 years
31 or more years	Every 3 - 5 years

This only applies to first-degree relatives (i.e. parents, brother/sister and children) of someone with HCM. If anyone in the family is having any symptoms suggesting a heart problem, they should see a cardiologist.

Communicating Hypertrophic Cardiomyopathy (HCM) Genetic Test Results

INFORMATION FOR PARTICIPANTS

Introduction

You are invited to take part in a research study examining how we can best communicate genetic test results in hypertrophic cardiomyopathy (HCM). Genetic testing for genetic heart diseases like HCM has become increasingly complex and our method of explaining these results needs to evolve to meet these changing needs. Cardiac genetic counsellors coordinate the genetic testing process and they play a key role in ensuring the information you are receiving is clear and meaningful for you and your family. The objective of this study is to compare the effectiveness of an intervention aimed at improving the way we communicate genetic test result information with our current usual care. If you consent to the study, you will be randomly assigned to either the new communication intervention or to usual care.

Individuals with hypertrophic cardiomyopathy are eligible to participate in this study if they are the first in their family to have genetic testing. People aged 16 years or older are eligible to participate; however children younger than this are excluded.

The study is being conducted by Dr Jodie Ingles, Prof Christopher Semsarian, Ms Laura Yeates and Ms Charlotte Burns from the Molecular Cardiology Research Program, Centenary Institute and Royal Prince Alfred Hospital Sydney.

Study Procedures

If you agree to participate in this study, you will be asked to complete the participant consent form. You will then be randomly allocated to one of two groups, to receive your genetic test result. Two weeks after your genetic test result appointment, you will be asked to complete a survey (*either paper or online*), asking about your understanding of genetic testing for HCM. This survey will take between 10-20 minutes to complete.

In addition, the researchers would like to phone you at one, three and six month intervals to follow up with you after you receive your genetic result. These phone calls will take approximately 10 minutes and will be conducted at a time that suits you.

1 Researchers will have access to your medical record to obtain information relevant
2 to this study. Information about you may also be sought from the *Australian Genetic*
3 *Heart Disease Registry*, if you have enrolled (www.heartregistry.org.au).
4 Confidentiality of the survey responses will be paramount. Your name will be
5 replaced with a unique code and only Dr Jodie Ingles will have access to the true
6 identity of respondents.
7

8
9 No additional genetic testing will be carried out as part of this study.

10
11 Information collected about you will be securely stored.
12

13 **Benefits**

14
15 While we intend that this research study furthers medical knowledge and may
16 improve management of genetic heart diseases in the future, it may not be of direct
17 benefit to you.
18

19 **Voluntary Participation**

20
21 Participation in this study is entirely voluntary. You do not have to take part in it. If
22 you do take part, you can withdraw at any time without having to give a reason.
23 Whatever your decision, please be assured that it will not affect your medical
24 treatment or your relationship with the staff who are caring for you.
25

26 **Confidentiality**

27
28 All of the information collected from you for the study will be treated confidentially,
29 and only the researchers named above will have access to it. The study results may
30 be presented at a conference or in a scientific publication, but individual participants
31 will not be identifiable in such a presentation.
32

33
34 Any forms completed online, including the participant consent form and survey will
35 be extremely secure to maintain participant privacy.
36

37 **Further Information**

38
39 When you have read this information, one of the investigators is available to discuss
40 it with you further and answer any questions you may have. If you would like to
41 know more at any stage, please feel free to contact:
42

Communicating Hypertrophic Cardiomyopathy (HCM) Genetic Test Results

PARTICIPANT CONSENT FORM

FOR PEER REVIEW ONLY

I, [name]
of [address]
..... [email]

have read and understood the Information for Participants on the abovenamed research study
and have discussed the study with

I have been made aware of the procedures involved in the study.

I understand that my participation in this study will allow the researchers to have access to my
medical record, including information held by the Australian Genetic Heart Disease Registry (if
I am enrolled), and I agree to this.

I freely choose to participate in this study and understand that I can withdraw at any time.

I also understand that the research study is strictly confidential.

I hereby agree to participate in this research study.

NAME:

SIGNATURE:

DATE:

NAME OF WITNESS:

SIGNATURE OF WITNESS:

Hello, this is (Insert Name) from the Centenary Institute, may I please speak to (Participant name)?

I am phoning (as we discussed back in (insert month of genetic result return) to follow up with you after you received your genetic result as part of our research into communicating genetic results. This is your (one month, three month, six month) follow up phone call. I was hoping to get some additional information from you regarding your gene result. Do you have 10 minutes or so to do this now- or I can arrange a more appropriate time?

SECTION 1: 3-generation pedigree documented – Have this documented prior to phone call. Confirm during phone call.

SECTION 2

**Who in the family have you told about the following: (List names/details):
Your diagnosis of HCM?**

About your genetic result?

**Who in the family has had an echo/ecg/Cardiology review- Outcome?
(Assess against guidelines)?**

Who in the family has had genetic testing- Outcome?

Who in the family is awaiting an appointment- with whom?

SECTION 3:

Total number of first degree relatives informed of diagnosis =

Total number of first degree relatives informed of genetic test outcome=

Total number of first degree relatives who have had cardiology review=

Total number of first degree relatives who have had genetic review=

Total number of first degree relatives awaiting review=

Total number of first degree relatives with a positive clinical screen=

Total number of relatives with a negative clinical screen =

Total number of first degree relatives with a positive genetic result =

Total number of first degree relatives with a negative genetic result=

Total number of other relatives informed =

Reporting checklist for protocol of a clinical trial.

Based on the SPIRIT guidelines.

Instructions to authors

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to include the missing information. If you are certain that an item does not apply, please write "n/a" and provide a short explanation.

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the SPIRIT reporting guidelines, and cite them as:

Chan A-W, Tetzlaff JM, Altman DG, Laupacis A, Gøtzsche PC, Krleža-Jerić K, Hróbjartsson A, Mann H, Dickersin K, Berlin J, Doré C, Parulekar W, Summerskill W, Groves T, Schulz K, Sox H, Rockhold FW, Rennie D, Moher D. SPIRIT 2013 Statement: Defining standard protocol items for clinical trials. *Ann Intern Med.* 2013;158(3):200-207

		Reporting Item	Page Number
Title	#1	Descriptive title identifying the study design, population, interventions, and, if applicable, trial acronym	1
Trial registration	#2a	Trial identifier and registry name. If not yet registered, name of intended registry	2, Table 1
Trial registration: data set	#2b	All items from the World Health Organization Trial Registration Data Set	9, Table 1
Protocol version	#3	Date and version identifier	1
Funding	#4	Sources and types of financial, material, and other support	18
Roles and responsibilities: contributorship	#5a	Names, affiliations, and roles of protocol contributors	1, 18
Roles and	#5b	Name and contact information for the trial	NA- No trial sponsor.

1	responsibilities:		sponsor	
2	sponsor contact			
3	information			
4				
5	Roles and	#5c	Role of study sponsor and funders, if any,	NA- no role other than
6	responsibilities:		in study design; collection, management,	funding for key
7	sponsor and		analysis, and interpretation of data;	researchers.
8	funder		writing of the report; and the decision to	
9			submit the report for publication, including	
10			whether they will have ultimate authority	
11			over any of these activities	
12				
13				
14				
15				
16	Roles and	#5d	Composition, roles, and responsibilities of	NA
17	responsibilities:		the coordinating centre, steering	
18	committees		committee, endpoint adjudication	
19			committee, data management team, and	
20			other individuals or groups overseeing	
21			the trial, if applicable (see Item 21a for	
22			data monitoring committee)	
23				
24				
25				
26				
27				
28	Background and	#6a	Description of research question and	4
29	rationale		justification for undertaking the trial,	
30			including summary of relevant studies	
31			(published and unpublished) examining	
32			benefits and harms for each intervention	
33				
34				
35				
36	Background and	#6b	Explanation for choice of comparators	11
37	rationale: choice			
38	of comparators			
39				
40				
41	Objectives	#7	Specific objectives or hypotheses	7,8
42				
43				
44	Trial design	#8	Description of trial design including type	9
45			of trial (eg, parallel group, crossover,	
46			factorial, single group), allocation ratio,	
47			and framework (eg, superiority,	
48			equivalence, non-inferiority, exploratory)	
49				
50				
51				
52	Study setting	#9	Description of study settings (eg,	9
53			community clinic, academic hospital) and	
54			list of countries where data will be	
55			collected. Reference to where list of study	
56			sites can be obtained	
57				
58				
59				
60				

1	Eligibility criteria	#10	Inclusion and exclusion criteria for participants. If applicable, eligibility criteria for study centres and individuals who will perform the interventions (eg, surgeons, psychotherapists)	9
2				
3				
4				
5				
6				
7				
8				
9	Interventions:	#11a	Interventions for each group with sufficient detail to allow replication, including how and when they will be administered	11
10	description			
11				
12				
13				
14				
15				
16	Interventions:	#11b	Criteria for discontinuing or modifying allocated interventions for a given trial participant (eg, drug dose change in response to harms, participant request, or improving / worsening disease)	NA
17	modifications			
18				
19				
20				
21				
22				
23				
24	Interventions:	#11c	Strategies to improve adherence to intervention protocols, and any procedures for monitoring adherence (eg, drug tablet return; laboratory tests)	NA- intervention was one clinic appointment
25	adherence			
26				
27				
28				
29				
30				
31	Interventions:	#11d	Relevant concomitant care and interventions that are permitted or prohibited during the trial	NA
32	concomitant care			
33				
34				
35				
36	Outcomes	#12	Primary, secondary, and other outcomes, including the specific measurement variable (eg, systolic blood pressure), analysis metric (eg, change from baseline, final value, time to event), method of aggregation (eg, median, proportion), and time point for each outcome. Explanation of the clinical relevance of chosen efficacy and harm outcomes is strongly recommended	12,13,14
