

## Expanded View Figures

**Figure EV1. No evidence for proliferation of near-plaque reactive gliosis.**

A, B The total density of astrocytes and microglia remained unchanged in APP/PS1-Stat3KO compared to APP/PS1-Stat3WT mice (Mann–Whitney test for both comparisons; APP/PS1-Stat3WT,  $n = 8$  (three females and five males) mice; APP/PS1-Stat3KO,  $n = 8$  (five females and three males) mice; age, 8–9 months).

C, D Using an anti-Ki67 antibody as a marker for cellular proliferation, we detected Ki67-positive cells (arrows) in the hippocampal dentate gyrus as a positive control. However, no Ki67 signal was detected around plaques (marked by arrowheads) of either APP/PS1-Stat3KO or APP/PS1-Stat3WT mice, indicating little-to-no glial proliferation (scale bars, 50  $\mu\text{m}$ ; same mice as in A and B).

Data information: Data are represented as mean  $\pm$  SEM.

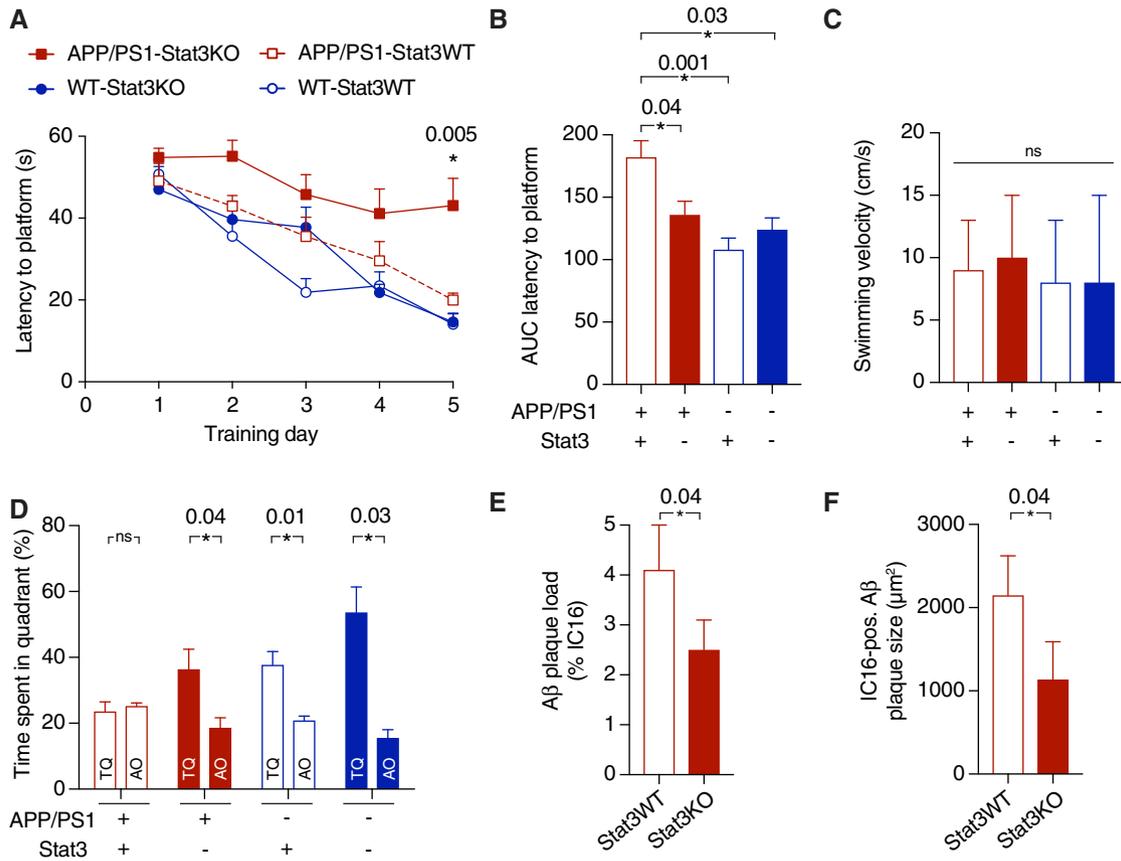

**Figure EV2. No significant morphological changes in glial cells remote from plaques.**

A–D The morphology of hippocampal astrocytes remote from plaques was largely unaltered in APP/PS1-Stat3KO compared to APP/PS1-Stat3WT mice.

E–H Similarly, the morphology of hippocampal microglia remote from plaques was also similar in APP/PS1-Stat3KO compared to APP/PS1-Stat3WT mice.

Data information: Data are represented as mean  $\pm$  SEM. Mann–Whitney test for all comparisons; scale bars, 20  $\mu\text{m}$ ; APP/PS1-Stat3KO,  $n = 10$  (four females and six males) mice; APP/PS1-Stat3WT,  $n = 6$  (three females and three males) mice; age, 8–9 months.

**Figure EV3. Persistence of cognitive protection and reduced amyloid pathology in late-stage APP/PS1-Stat3KO mice.**

- A Spatial learning and memory were assessed in the Morris Water Maze. APP/PS1-Stat3KO mice showed faster latencies to reach the hidden platform compared with APP/PS1-Stat3WT on day 5, but were similar to WT-Stat3WT and WT-Stat3KO mice (\* $P < 0.05$ , two-way repeated-measures ANOVA followed by Bonferroni post hoc test;  $P$ -value for APP/PS1-Stat3KO versus APP/PS1-Stat3WT mice).
- B, C The area under the curve (AUC) for the latency to reach the hidden platform was similar in APP/PS1-Stat3WT compared to WT-Stat3WT and WT-Stat3KO mice, but significantly higher in APP/PS1-Stat3KO mice (\* $P < 0.05$ , Kruskal–Wallis test followed by Dunn’s multiple comparisons test). The swimming velocity was similar in all groups (Kruskal–Wallis test followed by Dunn’s multiple comparisons test).
- D In the probe trial, APP/PS1-Stat3KO, WT-Stat3WT, and WT-Stat3KO mice spent significantly more time in the target quadrant (TQ) compared to the mean of all other quadrants (AO), whereas APP/PS1-Stat3WT spent equal times in the target and all other quadrants (\* $P < 0.05$ , Wilcoxon matched-pairs signed rank test for each comparison).
- E, F Plaque load and plaque size were reduced in APP/PS1-Stat3KO compared to APP/PS1-Stat3WT mice (\* $P < 0.05$ , Mann–Whitney test for both comparisons; same mice as in A–D).

Data information: Data are represented as mean  $\pm$  SEM. WT-Stat3WT,  $n = 12$  (6 females and 6 males) mice; WT-Stat3KO,  $n = 10$  (4 females and 6 males) mice; APP/PS1-Stat3WT,  $n = 12$  (seven females and five males) mice; APP/PS1-Stat3KO,  $n = 12$  (eight females and four males) mice; age, 13–14 months.
