1 **Generating Tn7 insertional libraries in *S. uvarum***

2 The plasmid library containing ligated *S. uvarum* genomic DNA with Tn7
3 insertion sites contains ~50,000 unique genomic insertion sites that were integrated into a
4 diploid and a haploid *MATa* strain (Figure 1B). We isolated mutants with the ClonNat
5 resistance marker on plates and created a final diploid pool of ~500,000 (10X coverage of
6 plasmid library) transformants (Figure 1B). The haploid pool was obtained from the
7 Caudy lab containing ~300,000 transformants. We added an additional 200,000
8 transformants to the haploid pool to increase the total coverage.

9 **Distribution of insertion sites across the *S. uvarum* genome**

10 We first sequenced the plasmid pool of *S. uvarum* mutants to determine the
11 genome coverage of genes containing insertion sites in the original plasmid library. We
12 sequenced the library by extracting plasmid DNA and enriching for fragments of DNA
13 containing the Tn7 sequence. Primers were designed to target the Tn7 sequence and the
14 Illumina linker sequences that were ligated to randomly sheared plasmid DNA (Figure
15 1C). The PCR amplicons of the Tn7 library were sequenced, trimmed, mapped and
16 processed through an in-house Ruby script to determine the position of the insertion site
17 (Material and Methods). Insertion sites with fewer than 10 reads were filtered out.
18 Detailed information about overall sequencing coverage is listed in **Supplemental Table**
19 **S4**. We used this same method to determine the insertion sites in the haploid and diploid
20 library by extracting genomic DNA from the pooled libraries. Haploid, diploid and
21 overlapping insertion sites are evenly distributed throughout the *S. uvarum* genome, as
22 illustrated in **Supplemental Fig. S1**.

1
2 **Supplemental Fig. S1. Distribution of haploid and diploid Tn7 insertions across the**
3 ***S. uvarum* genome.** Chromosomal map of sequenced transposon insertions wherein each
4 chromosome is represented by a rectangle outlined in black and numbered one through
5 sixteen from top to bottom. Haploid-only insertion sites are colored red, diploid-only
6 inserts are blue. Insertion sites that were identified in both libraries are indicated in
7 purple.

1 Once the insertion sites were determined in all three libraries, we counted the
2 number of insertion sites in each annotated open reading frame using an in-house Python
3 script (Materials and Methods). **Supplemental Table S11** summarizes the number of
4 insertion sites and the number of genes that contain insertion sites within the plasmid,
5 haploid and diploid libraries. All annotated *S. uvarum* genes containing the number of
6 insertion sites from each library are fully listed in **Supplemental Table S5**. Of the 5,908
7 annotated genes, a total of 5,315 (90%) genes harbor insertion sites that were identified in
8 at least one library. Comparisons between shared genes and unique genes with insertion
9 sites are illustrated in **Supplemental Fig. S2**. The number of genes with insertion sites
10 shared amongst all three libraries was 3,657 (69%) of the 5,315 genes summed across the
11 libraries. There are subsets of genes that are library specific or shared between two
12 libraries, likely due to differences in overall transformation coverage per library. There is
13 a subset of 742 genes, however, that is shared only between the diploid and plasmid
14 libraries (14%). Overall, only 3,933 genes harboring insertion sites were determined in
15 the haploid pool, suggesting that at least some of the genes falling out of the haploid pool
16 are likely to be essential based on their dispensability restrictions. We went on to test this
17 assumption using the known essential gene set in *S. cerevisiae*.

1 **Supplemental Table S11. Summary of library coverage.**

Library Type	Number of inserts > 10 reads	Number of inserts in ORFs	Number of genes with insert	% Genome covered	Number of orthologs with inserts	% Orthologs with inserts
Plasmid	54,351	33,394 (61.4%)	4,944	83%	4,630	85%
Diploid	46,326	27,121 (58.5%)	4,557	77%	4,283	79%
Haploid	42,904	22,988 (54.5%)	4,190	71%	3,933	72%

2 **Supplemental Fig. 2. Proportional Venn diagram summarizing the number of**
3 **insert-containing genes identified in each library.** Summary of genes containing at
4 least one insert sampled by 10 or more sequencing reads. The plasmid library is
5 represented in purple, the diploid pool in orange and the haploid pool in blue. Non-
6 overlapping regions represent genes that are library specific.

1 **Known *S. cerevisiae* essential genes contain fewer inserts than known non-essential**
2 **genes**

3 Although the large number of dropouts suggest that we have identified essential
4 genes, it is possible that these dropouts just reflect an incomplete library. To test if genes
5 in the haploid library without (or with minimal) insertion sites were likely to be essential,
6 we compared the haploid and diploid libraries to determine if differences in the number
7 of insertions between known essential and non-essential genes exist. Since the
8 essentiality of most genes is expected to be conserved between *S. cerevisiae* and *S.*
9 *uvarum*, we used the known essential set in *S. cerevisiae* to test if orthologous genes in
10 the haploid library contain fewer insertion sites. We normalized the number of inserts
11 within each gene by the length of the gene (inserts/kb) and plotted the distribution of
12 normalized inserts within known essential genes and non-essential genes in both diploid
13 and haploid libraries (**Supplemental Fig. S3A & B**).

14 The distribution between known *S. cerevisiae* essential and non-essential genes is
15 similar in the diploid pool, with no significant differences between gene types (essential
16 average inserts/kb=3.8 vs non-essential average inserts/kb = 4.2) (**Supplemental Fig.**
17 **S3C**, Wilcoxon test p-value = 0.2001). However, the distributions in known *S. cerevisiae*
18 essential and non-essential genes in the haploid library are significantly different, with
19 known essential genes averaging fewer normalized inserts per kb (known essential
20 average inserts/kb=0.88 vs non-essential average inserts/kb = 4) (**Supplemental Fig.**
21 **S3D**, Wilcoxon test p-value $<2.2 \times 10^{-16}$). This result suggests that the known conserved
22 essential genes can be predicted from the number of inserts in the haploid library. We
23 note that known *S. cerevisiae* essential genes in the haploid library harboring several
24 insertion sites are detected as well. We predict that these genes are candidate *S.*

- 1 *cerevisiae*-specific essential genes, and may not be essential in *S. uvarum*. We explore
- 2 these genes more fully in the following sections.

1
2 **Supplemental Fig. S3. Comparison of insertion distributions between haploid and**
3 **diploid libraries amongst known *S. cerevisiae* essential and non-essential genes.** A)
4 Density plot displaying the distribution of the normalized number of insertion sites in
5 known *S. cerevisiae* essential and non-essential genes within the *S. uvarum* diploid and
6 B) haploid libraries. C) Box plot of normalized insertions per kb in known *S. cerevisiae*
7 essential and non-essential genes in the diploid library. No significant difference was
8 detected between known essential and non-essential genes (Wilcoxon test $p = 0.2001$).
9 Essential average inserts/kb = 3.8 (SD = 3.98) vs. non-essential average inserts/kb = 4.2
10 (SD = 4.2). D) Box plot of normalized insertions per kb in known *S. cerevisiae* essential
11 and non-essential genes in the haploid library displaying a significant difference between
12 known essential and non-essential genes (Wilcoxon test $p < 2.2 \times 10^{-16}$). Essential
13 average inserts/kb = 0.88 (SD = 1.28) vs. non-essential average inserts/kb = 4 (SD =
14 4.38).

1 **Predicting *S. uvarum* essential and non-essential genes using an insertion ratio**
2 **metric**

3 Once we determined that essential genes contain significantly fewer insertion sites
4 than non-essential genes in the haploid library, we created a metric for determining a cut
5 off value to categorize predicted *S. uvarum* essential and non-essential genes. Due to the
6 nature of the library, insertional events at different positions across a gene may result in a
7 partial loss of function, meaning that even essential genes may still tolerate some
8 insertions. Therefore, we relied on comparisons between the diploid and haploid libraries
9 to make inferences about gene essentiality. Specifically, we calculated an insertion ratio
10 using the number of inserts per gene in the haploid library divided by the number of
11 inserts in the diploid library, which inherently normalizes for the length of the gene
12 (Materials and Methods). Using the insertion ratio as a metric, we tested if significant
13 differences exist between *S. uvarum* genes whose orthologs are known to be essential and
14 non-essential in *S. cerevisiae*, as well as *S. uvarum* intergenic regions. Intergenic regions
15 between convergent orientated genes are expected to not be essential, thus, the
16 distribution of intergenic regions is expected to be similar to that of non-essential genes
17 and represents our null distribution.

18 We note the significant difference that also exists between non-essential genes
19 and intergenic regions and attribute this difference to the possible genes that are
20 differentially essential between species in this category in comparison to intergenic
21 regions in *S. uvarum*. We note these differences are of a lesser magnitude than those that
22 exist between known essential genes. Once we established the intergenic region as
23 our null distribution, we ranked the insertion ratio value for each gene against the

1 intergenic distribution and determined the proportion of intergenic regions whose
2 insertion ratio was greater than the insertion ratio of that gene. Using this raking
3 metric, we set a cut-off value of 0.25 to categorize all annotated *S. uvarum* genes into
4 essential and non-essential categories. We chose this cut off metric to be more
5 inclusive than restrictive to be more likely to identify essential genes that are
6 species specific, despite the likelihood of increasing our false positive rate. A list of
7 all genes with their predicted classification can be found in **Supplemental**
8 **Table S7**.
