

# **SUPPLEMENTAL MATERIAL**

## Data S1.

### SUPPLEMENTAL METHODS

#### Characterization of hiPSC-derived cardiomyocytes

Cells were cultured in Matrigel-coated plates with mTeSR-1 culture medium (Stemcell Tech, USA) and passaged every 4-5 days. The protocol used to differentiate hiPSCs into CMs has been described previously<sup>1, 2</sup>. Briefly, undifferentiated hiPSCs were expanded on a Matrigel-coated dish for 4 days; then, differentiation was induced by culturing the cells with CHIR99021 in RPMI basal medium plus B27 without insulin (B27-). Twenty-four hours later, the cells were recovered and cultured with RPMI basal medium plus B27- for 2 days, in RPMI basal medium with B27- and the Wnt-signaling inhibitor IWR-1 for 48 hrs, and in RPMI/B27- alone for 48 hrs; then, 5 µM insulin was added. Beating cardiomyocytes usually appeared on day 8 of the differentiation protocol, and hiPSC-CMs were characterized via immunostaining for the expression of cardiac troponin T (cTnT), Connexin 43, and MLC2v.

#### Characterization of hiPSC-derived endothelial cells

hiPSCs were differentiated into ECs performed as previously described<sup>3, 4</sup>. Briefly, the undifferentiated cells were treated with a GSK-3β inhibitor and ascorbic acid to induce mesoderm differentiation. Five days later, cells that expressed CD34 (i.e., hiPSC-derived vascular progenitor cells [hiPSC-VPCs]) were collected via magnetic nanoparticle selection; then, the hciPSC-VCs were differentiated into ECs by culturing them on fibronectin-coated flasks with EC-developmental medium (EGM2-MV; Lonza, Basel, Switzerland). ECs were characterized via the expression of CD31, CD144.

#### Telomerase activity

Telomerase activity performed as previously described<sup>5</sup>. Briefly, Telomerase activity was measured with a TRAPeze Telomerase Detection Kit (Cat# S7700, Millipore, Inc.); the lysis buffer and inactivated hiPSCs were used as negative controls. Briefly,  $1 \times 10^6$  cells were added to 200 µL of 1x Chaps cell lysis buffer, incubated at 4°C for 30 minutes, and centrifuged at 14,000 rpm for 20 minutes; then, the supernatants were collected and stored at -80 °C. Protein concentrations were determined by the Bradford method and adjusted to 1 µg/µL; then, 1 µL of the protein sample was incubated at 30°C with 49 µL of Telomeric Repeat Amplification Protocol Reaction Mix (20 mM Tris-HCl, pH 8.3, 1.5 mM MgCl<sub>2</sub>, 63 mM KCl, 0.05% Tween-20, 1 mM EGTA, 0.05 mM dNTP, and diethylpyrocarbonate-treated water) for 30 minutes and heated at 95°C for 5 minutes to inactivate the telomerase. The samples were amplified for 30 PCR cycles, and each cycle consisted of denaturation at 95°C for 30 seconds, annealing at 59°C for 30 seconds, and extension at 72°C for 1 minute. The cycling period was followed by a single extension period at 72°C for 7 minutes. The PCR products were separated on 12% non-denaturing polyacrylamide gels and stained with 1:10,000 GelRed nucleic acid gel staining reagent (Cat# 41008, Biotium Inc), and the signal was visualized with a Chemidoc imaging system (Cat# 17001402, Bio-Rad Laboratories Inc). Relative telomerase activity was calculated as the ratio of the intensity of the telomerase product ladder to that of the 36-base pair (bp) internal control band and was normalized to the

protein concentration in each sample. Quantification was performed with NIH Image-J1.36b software.

### **Western blotting**

Cells were lysed with RIPA buffer (Sigma) and protease inhibitors; then, proteins (10 µg) were separated via 4-20% SDS-PAGE and Western-blotted with the corresponding antibodies (Supplemental Table 1), Precast Protein Gels (Bio-Rad), and Trans-Blot Turbo Mini PVDF Transfer Packs (Bio-Rad) as described previously<sup>5</sup>. GAPDH protein levels were also determined to confirm equal loading.

### **Transmission electron microscopy (TEM)**

Spheroids were fixed with 2.5% (vol/vol) glutaraldehyde over night at 4 °C, followed with three washes with PBS (15 min each) and post-fixed with 1% osmium tetroxide for 3 h. The samples were washed in PBS, dehydrated in graded ethanol (50%, 70%, 90% and 100%) and then in propylene oxide for 10 min. Next, samples were embedded, sectioned at about 70-nm thickness and stained with lead citrate. Micrographs were captured using a Morgagni 268 transmission electron microscope (FEI Company, The Netherlands) at 80 kV.

### **Mutation analysis**

Multiple alignments of B2M and CIITA amino acid sequences from WT and KO were done by Clustal<sup>6</sup>. Pathogenic potential of identified indel mutations WT and KO hiPSC was predicted by different web servers such as ExPASy - Translate tool and ATGpr<sup>7</sup>.

### **Statistical Analysis**

All values are expressed as mean ± standard error of mean (SEM), and were tested for significance level of type I error ( $P<0.05$ ) via the Student's t test or ANOVA for differences between the values.

**Table S1. Antibodies.**

Antigen	Vendor	Catalog#	Type	WB	IF	FC	Stim	PS
<b>GAPDH</b>	Cell Signaling Technology	3683S	Rabbit mAb	Yes

### **Supplemental Video Legends:**

**Video S1.** WT hiPSC differentiated cardiomyocytes derived spheroid synchronous contractile activity of individual spheroids in culture. Best viewed with Windows Media Player.

**Video S2.** KO hiPSC differentiated cardiomyocytes derived spheroid synchronous contractile activity of individual spheroids in culture. Best viewed with Windows Media Player.

**Video S3.** WT spheroid co-culture with PBMC for 5 days will result in the loss of spontaneous and synchronous contractile activity of individual spheroids in culture. Best viewed with Windows Media Player.

**Video S4.** KO spheroid co-culture with PBMC for 5 days will result in no change of spontaneous and synchronous contractile activity of individual spheroids in culture. Best viewed with Windows Media Player.
