Supplemental Figure Captions

Figure S1. Cortical Parcellation and group average correlation values. (a) 324 region of interest parcellation from Gordon & Laumann et al., 2014. Regions are color coded by RSN membership. The average Fisher z-transformed correlation matrices are shown for all 457 subjects following Type A processing (b) and for 435 retained subjects following Type B processing (c).

Figure S2: Pervasive high frequency noise in unfiltered FD traces. (a) The top panel shows 1200 frames of raw FD values (red trace) for subject 519950. The black line indicates a 0.2 FD cutoff for frame censoring, as implemented previously (Power et al. 2012, 2014). The panel second from the top shows FD values after low pass filtering with a 0.3Hz Butterworth filter (red trace) for the same run, with the black line indicating a 0.025 FD cutoff. The third and fourth panels show the corresponding DVARS values (blue trace), mean global signal (black trace), and gray plot. The frames that would be censored by use of the filtered FD values are well-aligned with peaks in the DVARS trace and perturbations in the gray plot characteristic of head motion (Power et al. 2012, 2014), whereas many more frames would be censored if the unfiltered FD values were used. (b) In some HCP R-fMRI runs, FD and DVARS do not correspond as well. Observe that for subject 510326 there are several peaks in the DVARS trace between frames 100 and 400 that are well-aligned with perturbations in the gray plot characteristic of head motion (Power et al. 2012, 2014); however, these peaks are not reflected in either FD trace (see black arrows). Thus, a DVAR threshold of 105% of median was used for scrubbing. (c) Spectrogram of FD traces before averaged across all runs from all subjects before (top) and after (bottom) low-pass filtering to remove the respiration peak. Prior to filtering, a peak is present above 0.3 hz (black arrow), consistent with respiration.

11 Behavioral Measures

12
13
14
15 To generate a list of 120 measures of potential neurobiological interest, the
16 following exclusion criteria (adapted from Smith et al., 2015) were applied:
17

- 18 1. 70 measures, which were quantitatively poor measures according to one
19 more of the following criteria:
20
21 a. A measured contained very extreme outlier values, as measured by
22 most extreme value from the median. Specifically, if x_s is an SM value for
23 subject s , and $y_s = (x_s - \text{median}(x_s))^2$, we consider an SM to have
24 extreme outliers if $\max(y_s) > 100 \times \text{mean}(y_s)$.
25
26 b. Fewer than 250 subjects had valid measures (too much missing data).
27
28 c. Discreteness with severe imbalance, defined as $>95\%$ of all sub- jects
29 having the same SM value.
30
31
- 32 2. 190 measures from the T1-weighted structural brain analysis using
33 FreeSurfer (including volumes of subcortical structures, and average
34 thickness and surface area of many cortical regions) were excluded. The
35 only structural brain measure included was the cube-root of whole brain
36 volume (including ventricles).
37
38
- 39 3. 57 variables considered undesirable, in some cases because they are not
40 sufficiently likely to be measures relating to brain function, and in some
41 cases where “minor” measures are highly correlated with more major
42 related measures. Thus we removed: “Is the subject in college?”; “Is the
43 subject in a live-in relationship?”; “Is the subject born in Missouri?”; BMI

self-report; thyroid/hypothyroid/endocrine measures; menstruation- related measures; fluid intelligence secondary measures of skipped tests and reaction time (as we included the highly correlated major measure of correct responses); all minor Delayed Discounting measures (that is, all except for the two major ones of area-under-the-curve for \$200 and \$40,000); all minor Sustained Attention (Short Penn Continuous Performance Test) measures (keeping the major measures of sensitivity and specificity); the minor Verbal Episodic Memory (Penn Word Memory Test) measure of reaction time; the minor Emotion Recognition (Penn Emotion Recognition Test) measure of Correct Responses Median Response Time; the minor visual Contrast Sensitivity (Mars Contrast Sensitivity) measure of error count; Age (as age range was limited to 26-30); Handedness; Employment status; "Whether blood was drawn for testing and measured hematocrit levels?"; Walking Endurance and Gait Speed; Physical Grip Strength; four measures relating to family history; color vision and eyeglass correction..

4. 41 measures of substance use that were highly similar to included measures or of no interest. This included 24 measures relating to alcohol consumption, and 9 measures relating to tobacco use, 3 measures relating to marijuana use, and 5 measures relating to past use of other drugs.

The full list of the 120 subject measures that were retained:

 25
 26
 27

28 **Additional Cleaning Approaches not included in Type B processing**

29 **Confound Regression**

30
 31
 32
 33 Seven measures used by Smith and colleagues (Smith 2015) were regressed
 34 across subjects from every edge (i.e. the relationship between a pair of ROIs).
 35 Here, we also included hematocrit. Regression of these 8 measures was applied
 36 at the population level to FC data obtained using both Type A and Type B
 37 processing. The 8 confounds are listed in Figure 1.
 38
 39
 40
 41
 42

43 **CompCor**

44
 45 Multiple regressors were generated by decomposition of white matter (5
 46 regressors) and ventricle (5 regressors) timecourses using PCA (Behzadi et al.,
 47 2007). The mean gray matter regressor was excluded. In the CompCor
 48 processing regime, all other steps in Type B were unchanged.
 49
 50
 51

52 **Partial Correlation**

53
 54 Because partial correlation performs best using maximally temporally separated
 55 ROIs, the partial correlation processing stream was run using a 200-ROI ICA-
 56
 57
 58
 59
 60

1
2
3 based parcellation rather than the 324-ROI Gordon-Laumann parcellation (Smith
4 et al., 2013). Partial correlation was computed on Type A data using FSLNets
5 (Smith et al., 2004) with L2 regularization at $\rho = 0.01$.
6
