Response to Reviewers:	<p>Editor reports: Your manuscript "Genome sequence of the barred knifejaw <i>Oplegnathus fasciatus</i> (Temminck & Schlegel, 1844): the first chromosome-level draft genome in the family Oplegnathidae" (GIGA-D-18-00300R1) has been re-reviewed by our reviewers. Based on these reports, and my own assessment as Editor, I am pleased to inform you that it is potentially acceptable for publication in GigaScience, once you have carried out some final essential revisions suggested by our reviewers. Please also add the citation details for the GigaDB in the paper.</p> <p>Reply: Thanks a lot for the editor's suggestion. We have add the citation details for the GigaDB in the paper. We also have revised the time of our subject as "Oplegnathus fasciatus (Temminck & Schlegel, 1844)".</p> <p>Reviewer reports: Reviewer #1: The authors have restructured and considerably improved the manuscript, accommodating most of my suggestions. I have some final comments, which are mostly cosmetic:</p> <p>My previous comments 3/4, on the k-mer distribution - now at lines 112: this is still not very clear. I understand that the repeat content is based on fitting a model to the distribution. I do not fully agree that the peak labeled as repeated k-mers should be identified with generic repeat content, I think these are very clearly duplications (which are, of course, technically repeat content).</p> <p>I would suggest to clarify the genome size calculation itself, which is now incorrect (line 112): $8.09 \times 10^{10} / 100 = 777.5 \text{ Mb}$.</p> <p>Reply: We agreed with the reviewer's comment on that the peak labeled as repeated k-mers should be identified as generic repeat content. Strictly speaking, the majority of k-mers after the 1.8 times larger than the main depth (100 in our case) were most likely from the repeated regions, including the duplications that mentioned in the comment. That is also the way we estimated the repeat ratio of the genome. We are sorry that the method for the genome size estimation was not clear enough. To clarify the method, the following formula were used : genome size = $(Nk\text{-mer} - Nerror_k\text{-mer}) / D$, where G is genome size, Nk-mer is the number of k-mers, Nerror_k-mer is the number of k-mers with the depth of 1, and D is the k-mer depth. The number of k-mers with depth of 1 were eliminated since k-mers with low depth were likely from the sequencing errors. As a result, the genome size was estimated as 777.5Mb. We have revised the description of genome size estimation method in the manuscript.</p> <p>Line 132, 'complexity ... such as heterozygosity': This does not fit the very low heterozygosity levels just identified from the k-mer profile. Possibly structural variants instead of SNPs? I don't think the high duplication levels can explain this?</p> <p>Reply: We agreed with the reviewer's comment on that genome complexity derived from the structural variants might also increase size of the genome assembly. So we revised the sentence as "The genome complexity, such as structural variants and heterozygosity might be possible reasons to explain the relative large genome size in the assembly."</p> <p>Line 162: 'filter all base sequences than 500 bp': more than 500 bp? Less than 500 bp?</p> <p>Reply: We would like to give sincere thanks to reviewer's suggestions. We revised "filter all</p>

	<p>base sequences than 500 bp” as “filter all base sequences more than 500 bp”</p> <p>There is a lot of redundancy between tables 1 & 3, I would suggest either merging these or moving the finer details of the assembly to table 3 (and keep table 1 as an overview of the final results, just N50/genome size/coverage).</p> <p>Reply: Thanks a lot for the reviewer’s suggestion. We have merged the Table 3 to Table 1 to eliminate the information redundancy.</p> <p>Table 2 would be more appropriate in the supplementary information.</p> <p>Reply: Thanks a lot for the reviewer’s comment. The Table 2 was moved into the supplementary data according to the suggestion.</p>

29 **Abstract**

30 **Background**

31 The barred knifejaw (*Oplegnathus fasciatus*), a member of the Oplegnathidae family
32 of the Centrarchiformes, is a commercially important rocky reef fish native to East
33 Asia. *O. fasciatus* has become an important fishery resource for offshore cage
34 aquaculture and fish stocking of marine ranching in China, Japan and Korea. Recently,
35 sexual dimorphism in growth with neo-sex chromosome and widespread biotic
36 diseases in *O. fasciatus* has been received increasing concern. However, adequate
37 genome resources for gaining insight into sex-determining mechanisms and
38 establishing genetically resistant breeding systems for *O. fasciatus* are lacking. Here,
39 we analysed the entire genome of a female *O. fasciatus* fish using long-read
40 sequencing and Hi-C data to generate chromosome-length scaffolds and a highly
41 contiguous genome assembly.

42 **Findings**

43 We assembled the *O. fasciatus* genome with a total of 245.0 Gb of raw reads that were
44 generated using both PacBio Sequel and Illumina HiSeq 2000 platforms. The final
45 draft genome assembly was approximately 778.7 Mb, which reached a high level of
46 continuity with a contig N50 of 2.1 Mb. The genome size was consistent with the
47 estimated genome size (777.5 Mb) based on *k*-mer analysis. We combined Hi-C data
48 with a draft genome assembly to generate chromosome-length scaffolds. Twenty-four
49 scaffolds corresponding to the twenty-four chromosomes were assembled to a final
50 size of 768.8 Mb with a contig N50 of 2.1 Mb and a scaffold N50 of 33.5 Mb using
51 1,372 contigs. The identified repeat sequences accounted for 33.9% of the entire
52 genome, and 24,003 protein-coding genes with an average of 10.1 exons per gene
53 were annotated using *de novo* methods, with RNA-seq data and homologies to other
54 teleosts. According to phylogenetic analysis using protein-coding genes, *O. fasciatus*
55 is closely related to *Larimichthys crocea*, with *O. fasciatus* diverging from their
56 common ancestor approximately 70.5-88.5 million years ago.

57 **Conclusions**

58 We generated a high-quality draft genome for *O. fasciatus* using long-read PacBio
59
60
61

63
64
65

59 sequencing technology, which represents the first chromosome-level reference
60 genome for Oplegnathidae species. Assembly of this genome assists research into fish
61 sex-determining mechanisms and can serve as a resource for accelerating
62 genome-assisted improvements in resistant breeding systems.

63 *Keywords:* *Oplegnathus fasciatus*; chromosome-level genome assembly; Hi-C
64 assembly; sex-determining mechanism

65 **Data description**

66 **Introduction of *O. fasciatus***

67 The Oplegnathidae family belongs to the order Centrarchiformes, including only one
68 genus *Oplegnathus*, which is comprised of seven species (*O. conwayi*, *O. fasciatus*, *O.*
69 *insignis*, *O. peaolopesi*, *O. punctatus*, *O. robinsoni*, *O. woodwardi*), two of which (*O.*
70 *fasciatus* and *O. punctatus*) are commercially valuable in East Asia. The barred
71 knifejaw *O. fasciatus* (NCBI: txid 163134, Fishbase ID: 1709) (Temminck & Schlegel,
72 1844) is one of these two species in the *Oplegnathus*, which is commonly found at the
73 depth of one to ten metres in association with rocky reefs^{1,2}, and distributed across a
74 wide range of shallow waters around Korea, Japan, China and Hawaii^{1,3,4} (Fig. 1). *O.*
75 *fasciatus* has become an important fishery resource for offshore cage aquaculture and
76 fish stocking of marine ranching in China, Japan and Korea⁵. It has been reported that
77 the male of *Oplegnathus* possesses a neo-sex chromosome, possibly a sex
78 chromosome Y. The sex chromosome system for *Oplegnathus* is considered to be X₁
79 X₁ X₂ X₂ / X₁ X₂ Y based on karyotype analyses^{6,7}. Furthermore, sexual dimorphism
80 in growth has been detected in the *O. fasciatus*, with male fish exhibiting faster
81 growth than females, possibly be due to the sex chromosome system in *Oplegnathus*⁸.
82 *O. fasciatus* is vulnerable to viruses (e.g., Iridovirus) and genetic degradation caused
83 by inbreeding has led to higher susceptibility to diseases^{9,10}. It is vital to develop
84 genomic resources to gain insight into sex-determining mechanisms and to accelerate
85 the genome-assisted improvements in resistant breeding systems.

86 So far, a genome sequence with the chromosomal assembly of *O. fasciatus* has
87 not been reported. Here, we constructed a high-quality chromosome-level reference

1 88 genome assembly for *O. fasciatus* using long reads from the PacBio DNA sequencing
2 89 platform and a genome assembly strategy taking advantage of the genome assembly
3 90 program Canu¹¹. This genome assembly of *O. fasciatus* is the first chromosome-level
4 91 reference genome constructed for the Oplegnathidae family. The completeness and
5 92 continuity of the genome will provide high quality genomic resources for studies on
6 93 sex-determining mechanisms and for accelerating the genome-assisted improvements
7 94 in resistant breeding systems.
8
9

16 96 **Genomic DNA extraction, genome size estimation**

17 97 High-quality genomic DNA for sequencing using the Illumina platform (Illumina Inc.,
18 98 San Diego, CA, USA) and PacBio Sequel sequencing (Pacific Biosciences of
19 99 California, Menlo Park, CA, USA) was extracted from fresh muscle tissue and blood
20 100 samples from a single female *O. fasciatus*. The fish was collected from the near-shore
21 101 area of Qingdao city (Yellow Sea), Shandong province. The whole-genome size of *O.*
22 102 *fasciatus* was estimated based on Illumina DNA sequencing technology. A short-insert
23 103 library (300~350 bp) was constructed and generated a total of ~90.7 Gb of raw reads
24 104 using the standard protocol provided by the Illumina HiSeq X Ten platform (Illumina
25 105 Inc., San Diego, CA, USA). After the removal of low-quality and redundant reads, we
26 106 obtained approximately ~80.8 Gb of clean data for *de novo* assembly to estimate the
27 107 whole-genome size (S Table 1, Fig. 2). All cleaned reads were subjected to 17-mer
28 108 frequency distribution analysis¹². As the total number of *k*-mers were approximately
29 109 8.09×10^{10} and the peak of *k*-mers was at a depth of 100, the genome size of *O.*
30 110 *fasciatus* was calculated to be 777.5 Mb using the following formula with amendment:
31 111 $G = (N_{k\text{-mer}} - N_{\text{error}_k\text{-mer}}) / D$, where *G* is genome size, $N_{k\text{-mer}}$ is the number of *k*-mers,
32 112 $N_{\text{error}_k\text{-mer}}$ is the number of *k*-mers with the depth of 1, and *D* is the *k*-mer depth (Fig.
33 113 2). Meanwhile, an estimated heterozygosity of 0.29% and a repeat content of 38.46%
34 114 were detected for *O. fasciatus* in this work. A pilot genome assembly was
35 115 approximately 744.5 Mb with a contig N50 of 7.2 kb and a scaffold N50 of 84.1kb
36 116 using the Illumina data and the assembly program Platanus¹³ (S Table 2). The GC
37 117 content was 41% (S Fig. 1). This first attempt at a genome assembly was of

2 119

3
4 **120 Genome assembly using PacBio long reads**

5
6 121 Two 20 kb genomic DNA libraries were constructed and sequenced using the PacBio
7
8 122 Sequel platform, generating 62.9 Gb raw DNA reads. We obtained 4.8 million
9
10 123 subreads (62.8 Gb in total) with an N50 read length of ~22 kb after removing adaptor
11
12 124 (S Table 1).

13
14 125 Canu v1.4 (Canu, RRID:SCR_015880) was firstly used to assemble the genome
15
16 126 with the Corrected-Error-Rate parameter set at 0.040¹¹. As a result, a genome
17
18 127 assembly with a total length of 875.9 Mb was constructed for *O. fasciatus*, slightly
19
20 128 higher than the genome size estimated by 17-mer analysis based on the Illumina data
21
22 129 (S Table 2). The genome complexity, such as structural variants and heterozygosity
23
24 130 might be possible reasons to explain the relative large genome size in the assembly.
25
26 131 We therefore applied Redundans v0.13c¹⁴ to remove the sequence redundancy to
27
28 132 obtain a genome assembly size of 778.0 Mb. We then used the Arrow tool in SMRT
29
30 133 Link 5.0 software with the minCoverage parameter set at 15 to implement error
31
32 134 correction based on the PacBio long reads data (Table 1). The resulting genome
33
34 135 assembly was further polished using Illumina NGS data, which were used in the
35
36 136 genome survey analysis above. The final draft genome assembly was 778.7 Mb,
37
38 137 which reached a high level of continuity with a contig N50 length of 2.1 Mb (Table 1).
39
40 138 The contig N50 of *O. fasciatus* was much higher than those of previous fish genome
41
42 139 assemblies constructed using NGS DNA sequencing technologies and is comparable
43
44 140 to those of recently reported model fish species (S table 3). Previous studies
45
46 141 illuminated the relationship between read length and genome assembly; therefore, we
47
48 142 attributed the continuity of the genome primarily to the application of long reads in
49
50 143 the assembly.

51
52
53 **144 Hi-C library construction and chromosome assembly**

54
55 145 Hi-C is a sequencing-based approach for determining chromosome interactions by
56
57 146 calculating the contact frequency between pairs of loci, which are strongly dependent
58
59 147 upon the one-dimensional distance, in base pairs, between a pair of loci^{15,16}. In this
60
61
62
63
64
65

148 work, we used Hi-C to construct the genome assembly of *O. fasciatus*.

149 Genomic DNA was extracted for the Hi-C library from a whole-blood sample of
150 *O. fasciatus* as previously described¹⁷. Cells were fixed with formaldehyde and lysed,
151 and the cross-linked DNA was digested with MboI. Sticky ends were biotin-labelled
152 and proximity ligated to form chimeric junctions and then physically sheared to a size
153 of 300–500 bp¹⁷. Chimeric fragments representing the original cross-linked,
154 long-distance physical interactions were then processed into paired-end sequencing
155 libraries, and 629 million 150-bp paired-end Illumina reads (91.5 Gb) were produced
156 with Q20 and Q30 of ~94.0% (S Table 1, S Table 4). By mapping the Hi-C data to the
157 PacBio-based assembly using BWA software (BWA, RRID:SCR_010910), we found
158 that sequencing data with mates mapped to a different contig (or scaffold) and data
159 mapped to a different contig (or scaffold) (map Q5 \geq 5) were 593.7 Mb (94.4%),
160 240.5 Mb (40.5%) and 205.1 Mb (34.6%), respectively (S Table 4). We then further
161 employed BWA and Lachesis software to align paired-end reads to filter all base
162 sequences than 500bp from each restriction site¹⁸. According to the conduct of
163 clustering, ordering, and orienting to the assembly contigs (1,692), these sequences
164 were grouped into 24 chromosome clusters and scaffolded using Lachesis software
165 with tuned parameters¹⁹ (S Table 4, Fig. 3). Finally, we constructed the chromosome
166 interactions map using Juicer software and employed the JucieBox to complete the
167 visual correction of the interaction map. We obtained polished 1,756 polished contigs
168 by interrupting misassembly from 1,692 contigs. Twenty-four scaffolds were
169 assembled corresponding to the 24 chromosomes of *O. fasciatus* based on the
170 karyotype analyses^{6,7} (S Table 4, Fig. 3).

171 A final size of 768.8 Mb accounting for the 98.7% draft genome was assembled,
172 which showed a high level of continuity with a contig N50 of 2.1 Mb and a scaffold
173 N50 of 33.5 Mb using 1,372 contigs. The anchor rate of contigs (> 100 kb) to
174 chromosomes was attained up to the 99.7% based on the Hi-C assembly (Table 1).
175 The contig N50 and scaffold N50 of *O. fasciatus* were much higher than those of
176 previous fish genome assemblies constructed using NGS DNA sequencing
177 technologies based on the genome assembly using PacBio long reads and Hi-C

178 assembly (S table 3).

179

180 **Genome quality evaluation**

181 To assess the completeness of the assembled *O. fasciatus* genome, we subjected the
182 assembled sequences to BUSCO version 3 evaluation (BUSCO. RRID:SCR_015008)
183 (BUSCO, actinopterygii_odb9)²⁰. Overall, 96.6% and 1.5% of the 4,584 expected
184 actinopterygii genes were identified in the assembled genome as complete and partial
185 BUSCO profiles, respectively. Approximately 85 genes could be considered missing
186 in our assembly (S table 5). Among the expected complete actinopterygii genes, 4,259
187 and 171 were identified as single copy and duplicated BUSCOs, respectively (S table
188 5). We then used Minimap2 to estimate the completeness and homogeneity of genome
189 assembly based on CLR (Continuous Long Reads) subreads. A high quality of
190 completeness and homogeneity was assessed in the genome assembly, and the
191 mapping rate, coverage rate and average sequencing depth reached 90.2%, 99.9% and
192 80.6, respectively (S table 6). Note that the mapping ratio might be related to the
193 repetitive content of the *O. fasciatus* genome, especially for the high repeat content in
194 the sex chromosomes⁶. However, how the repetitive elements in the genome influence
195 the karyotypes of this species needs further investigation.

196 To further evaluate the accuracy of the *O. fasciatus* genome assembly, we
197 aligned the NGS-based short reads from the whole-genome sequencing data against
198 the reference genome using BWA²¹. We then used GATK (GATK,
199 RRID:SCR_001876) to implement SNP calling and filter work, and the results
200 showed that 99.8% and 0.2% of the 1.6×10^6 expected SNP reads were identified in
201 the assembled genome as heterozygous and homologous SNPs, respectively. SNP
202 calling on the final assembly also yielded a heterozygosity rate of 0.20%, supporting
203 the *k*-mer estimate analysis (0.29%) (S table 7).

204

205 **Repeat sequences within the *O. fasciatus* genome assembly**

206 To identify tandem repeats, we utilized Tandem Repeat Finder to annotate repetitive
207 elements in the *O. fasciatus* genome. RepeatModeler (RepeatModeler,

30
208 RRID:SCR_015027) (version 1.04) and LTR_FINDER (LTR_Finder,
209 RRID:SCR_015247)²² were used to construct a *de novo* repeat library with default
210 parameters. Subsequently, we used RepeatMasker (RepeatMasker,
211 RRID:SCR_012954)²³ (version 3.2.9) to map our assembled sequences on the
212 Repbase TE (version 14.04)²⁴ and the *de novo* repeat library to identify known and
213 novel transposable elements (TEs). In addition, TE-related proteins were annotated by
214 using RepeatProteinMask software (version 3.2.2)²³.

215 The identified repeat sequences accounted for 33.9% of the *O. fasciatus* genome
216 including repeat sequences with 23.6% of the genome based on the *de novo* repeat
217 library (Table 2). Approximately 23.4% of the *O. fasciatus* genome was identified as
218 interspersed repeats (most often TEs). Among them, DNA transposable elements were
219 the most abundant type of repeat sequences, which occupied 11.5% of the whole
220 genome. Long interspersed nuclear elements (LINEs) and long terminal repeats (LTRs)
221 comprised 7.3% and 4.0% of the whole genome, respectively (Table 2, S Fig. 2).

222 **RNA preparation and sequencing**

223 We sequenced cDNA libraries prepared from the eggs of *O. fasciatus* that were used
224 for genome annotation using Illumina sequencing technology. RNA quality was
225 determined based on the estimation of the ratio of absorbance at 260nm/280nm (OD =
226 2.0) and the RIN (value = 9.2) by using a Nanodrop ND-1000 spectrophotometer
227 (LabTech, USA) and a 2100 Bioanalyzer (Agilent Technologies, USA), respectively.
228 We used the Clontech SMARTer cDNA synthesis kit to complete reverse transcription.
229 A paired-end library was prepared following the Paired-End Sample Preparation Kit
230 manual (Illumina Inc., San Diego, CA, USA). Finally, a library with an insert length
231 of 300 bp was sequenced by Illumina HiSeq X Ten in 150PE mode (Illumina Inc., San
232 Diego, CA, USA). As a result, we obtained ~42.2 Gb high-quality transcriptome data
233 from RNA-seq (S Table 1, S table 8).

234 **Gene annotation**

235 Gene annotation of the *O. fasciatus* genome was performed using *de novo*,
236 homology-based and transcriptome sequencing-based predictions. We employed
237 Augustus (Augustus, RRID:SCR_008417) (version 2.5.5)²⁵ and GenScan

1 238 (GENSCAN, RRID:SCR_012902) (version 1.0)²⁶ software to predict protein-coding
2 239 genes in the *O. fasciatus* genome assembly. Protein sequences of closely related fish
3
4 240 species including *Larimichthys crocea*, *Lates calcarifer*, *Gasterosteus aculeatus*,
5
6 241 *Paralichthys olivaceus*, *Cynoglossus semilaevis* and *Gadus morhua* were downloaded
7
8 242 from Ensembl²⁷ and aligned against the *O. fasciatus* genome using TBLASTN
9
10 243 (TBLASTN, RRID:SCR_011822) software²⁸. Subsequently, Genewise2.2.0
11
12 244 (GeneWise, RRID:SCR_015054) software²⁹ was employed to predict potential gene
13
14 245 structures on all alignments.

16 246 We also mapped these NGS transcriptome short reads onto our genome assembly
17
18 247 using TopHat1.2 (TopHat, RRID:SCR_013035) software³⁰, and then we employed
19
20 248 Cufflinks (Cufflinks, RRID:SCR_014597)³¹ to predict gene structures (S table 9). All
21
22 249 gene models were then integrated using MAKER (MAKER, RRID:SCR_005309) to
23
24 250 obtain a consensus gene set³². The final total gene set was composed of 24,003 genes
25
26 251 with an average of 10.1 exons per gene in the *O. fasciatus* genome (Table 1). The
27
28 252 gene number, gene length distribution, CDS length distribution, exon length
29
30 253 distribution and intron length distribution were all comparable with those of other
31
32 254 teleost fish species (S table 9, S Fig. 3).

33 255 To obtain further functional annotation of the protein-coding genes in the *O.*
34
35 256 *fasciatus* genome, we employed the local BLASTX (BLASTX, RRID:SCR_001653)
36
37 257 and BLASTN (BLASTN, RRID:SCR_001598) programs and the Swiss-prot database
38
39 258 with an e-value $\leq 1e-5^{33}$ to align the non-redundant nucleotide (NT) and
40
41 259 non-redundant protein (NR), respectively. We also used Blast2GO (Blast2GO,
42
43 260 RRID:SCR_005828) software to search the Gene ontology (GO), and Kyoto
44
45 261 Encyclopaedia of Genes and Genomes (KEGG) pathway databases^{34, 35, 36}. Ultimately,
46
47 262 97.3% (23,364 genes) of the 24,003 genes were annotated by at least one database (S
48
49 263 Table 10). Four types of non-coding RNAs (microRNAs, transfer RNAs, ribosomal
50
51 264 RNAs, and small nuclear RNAs) were also annotated using the tRNAscan-SE
52
53 265 (tRNAscan-SE, RRID:SCR_010835) and the Rfam database^{37, 38} (S Table 11).

54 266 **Gene family identification and phylogenetic tree construction**

55 267 We employed the BLASTP (BLASTP, RRID:SCR_001010) program³⁹ with an
56
57
58
59
60
61
62
63
64
65

1 268 e-value threshold of 1e-5 to identify gene families based on the transcript alignments
2
3 269 of each gene from *O. fasciatus* and other fish species, which included *Larimichthys*
4
5 270 *crocea*, *Gadus morhua*, *Paralichthys olivaceus*, *Cynoglossus semilaevis*, *Notothenia*
6
7 271 *coriiceps*, *Boleophthalmus pectinirostris*, *Lepisosteus oculatus*, *Gasterosteus*
8
9 272 *aculeatus*, *Callorhinchus milii*, *Danio rerio*, *Salmo salar* and *Oryzias latipes*. 21,528
10
11 273 gene families were identified by clustering the homologous gene sequences based on
12
13 274 H-scores calculated from Bit-score using Hcluster_sg software (S Fig. 4).
14
15 275 Subsequently, we selected 1,236 single-copy orthogroups from the above-mentioned
16
17 276 species to construct the phylogenetic relationship between *O. fasciatus* and other fish
18
19 277 species. We used the ClustalW (ClustalW, RRID:SCR_002909) program⁴⁰ to extract
20
21 278 and align coding sequences of single-copy genes from the 1,158 orthogroups with a
22
23 279 length filter (S Fig. 5). All the alignments were concatenated as a single data set for
24
25 280 each species. Nondegenerated sites extracted from the data set were then joined into
26
27 281 new sequences for each species to construct a phylogenetic tree based on the
28
29 282 maximum-likelihood method implemented in the PhyML package⁴¹ (with the -m
30
31 283 PROTGAMMAAUTO model). We used the MCMCtree program to estimate
32
33 284 divergence times among species based on the approximate likelihood method⁴² and
34
35 285 molecular clock data from the divergence time between medaka from the TimeTree
36
37 286 database⁴³. According to the phylogenetic analysis, *O. fasciatus* (Eupercaria:
38
39 287 Centrarchiformes) clustered with *Larimichthys crocea* in the order Perciformes
40
41 288 (Eupercaria), which was consistent with the new fish species taxonomy⁴⁴ (Fig. 4). The
42
43 289 divergence time between *O. fasciatus* and the common ancestor with *Larimichthys*
44
45 290 *crocea* was at approximately 70.5-88.5 Ma.

47 291 **Conclusions**

48
49 292 We successfully assembled the genome of *O. fasciatus* and reported the first
50
51 293 chromosome-level genome sequencing, assembly and annotation based on long reads
52
53 294 from the third-generation PacBio Sequel sequencing platform. The final draft genome
54
55 295 assembly is approximately 778.7 Mb, which was slightly higher than the estimated
56
57 296 genome size (777.5 Mb) based on *k*-mer analysis. Those contigs were scaffolded to
58
59 297 chromosomes using Hi-C data, resulting in a genome with a high level of continuity.
60
61
62
63
64
65

1 298 With a contig N50 of 2.1 Mb and a scaffold N50 of 33.5 Mb. The chromosome-level
2 299 genome assembly of *O. fasciatus* also being the first high-quality genome in the
3
4 300 Oplegnathidae family. We also predicted 24,003 protein-coding genes from the
5
6 301 generated assembly, and 97.3% (23,364 genes) of all protein-coding genes were
7
8 302 annotated. We found that the divergence time between *O. fasciatus* and its common
9
10 303 ancestor with *Larimichthys crocea* was approximately 70.5-88.5 Ma. As far as we
11
12 304 known, the Y chromosomes has always exhibited many specific sequence
13
14 305 characteristics compared to X1 and X2, such as repeat content, and those differences
15
16 306 might increase the difficulty of the sequence assembly of chromosomes X1 and X2.
17
18 307 The chromosome-level genome assembly together with gene annotation data
19
20 308 generated for the female fish in this work will provide a valuable resource for further
21
22 309 research on sex-determining mechanisms, especially for obtaining an accurate
23
24 310 assembly of the Y chromosome in male fish. These results will also accelerate
25
26 311 genome-wide association studies in resistant breeding systems.

Table 1 Summary of *Oplegnathus fasciatus* genome assembly and annotation

Genome assembly		
	Draft scaffolds	Chromosome-length scaffolds based on Hi-C
Length of genome (bp)	778,731,089	768,808,243
Number of contigs	1,692	1,372
Contigs N50 (bp)	2,149,025	2,130,780
Number of scaffold	/	24
Scaffold N50 (bp)	/	33,548,962
Genome coverage (X)	314.6	
Number of contigs (≥ 100 kb)	693	708
Total length of contigs (≥ 100 kb)	735,235,962	732,827,446
Mapping rate of contigs (≥ 100 kb) (%)	/	99.67
Genome annotation		
Protein-coding gene number	24,003	
Mean transcript length (kb)	16.1	
Mean exons per gene	10.1	
Mean exon length (bp)	217.7	
Mean intron length (bp)	1527.4	

Table 2 The detailed classification of repeat sequences of *Oplegnathus fasciatus*

Type	Rebase TEs		TE proteins		De novo		Combined TEs	
	Length (bp)	% in genome	Length (bp)	% in genome	Length (bp)	% in genome	Length (bp)	% in genome
DNA	39,147,527	5.03	5,390,266	0.69	93,089,344	11.95	124,417,402	15.98
LINE	23,983,322	3.08	16,460,762	2.11	57,167,551	7.34	85,761,250	11.01
SINE	875,585	0.11	0	0.00	914,559	0.12	1,747,250	0.22
LTR	10,163,601	1.31	5,770,483	0.74	31,126,639	4.00	42,465,968	5.45
Satellite	2,028,992	0.26	0	0.00	2,613,480	0.34	4,361,048	0.56
Simple_repeat	1,556,026	0.20	0	0.00	5,179,965	0.67	6,386,303	0.82
Other	6,545	0.00	0	0.00	0	0.00	6,545	0.00
Unknown	331,430	0.04	0	0.00	20,636,768	2.65	20,967,052	2.69
Total	73,544,786	9.44	27,613,880	3.55	183,954,095	23.62	250,611,845	32.18

Figure Legends

Fig. 1 A representative individual of *O. fasciatus*

Fig. 2 *k*-mer distribution of the *O. fasciatus* genome

Fig. 3 Hi-C interaction heatmap for *O. fasciatus* reference genome, showing interactions between the 24 chromosomes

Fig. 4 The phylogenetic relationships of *O. fasciatus* with other fishes. The bootstrap values (larger than 1) calculated from 1000 bootstrap replicates and the branch lengths (smaller than 1) were labelled at and below/above each branch, respectively
