

BMJ Open

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email info.bmjopen@bmj.com

Abstract

Objectives: Evolution of multimorbidity describes the continuum from healthy status, development of a single disease, and further progression to multimorbidity with additional diseases. We aim to investigate the evolution of cardiometabolic multimorbidity and their risk of mortality in a Chinese population.

Design: longitudinal cohort study: the CHinese Electronic health Records Research in Yinzhou (CHERRY) study during 5.43 million person-years follow-up (median 5.16 years).

Participants: Data from 1,038,704 adults (total 22,750 death) was analyzed.

Exposure: Cardiometabolic multimorbidity was defined as ever diagnosis of two or more following diseases: hypertension, diabetes and cardiovascular diseases (CVD).

Primary and secondary outcome measures: Age- and sex-adjusted hazard ratios (HRs) were calculated for all-cause mortality.

Results: Totally 105,209(10.1%) individuals changed their cardiometabolic disease status during follow-up. The prevalence of cardiometabolic multimorbidity increased from 2.41%(2.38%-2.44%) to 5.94%(5.90%-5.99%). Using baseline status of multimorbidity, the HRs were 1.37(1.33-1.42), 1.71(1.64-1.79) and 2.22(2.00-2.46) in patients with one, two or three diseases respectively. Among all combinations, patients with history of CVD only or diabetes and CVD were highest, i.e. 3.31(3.05-3.59) and 3.12(2.37-4.11) respectively, whereas patients with hypertension only had the lowest HR as 1.26(1.22, 1.30). In contrast, considering the longitudinal information, the HRs were 1.36(1.32-1.41), 2.03(1.96-2.10) and 2.16(2.05, 2.29) in patients with one, two or three diseases respectively.

Conclusions: The prevalence of patients having cardiometabolic comorbidity in a general population was more than doubled within 5 years, indicating rapid evolution

1
2
3 of cardiometabolic multimorbidity in Chinese. Among all combinations, history of
4 CVD dominates the risk with mortality. A complementary strategy is needed in
5
6 China.

1 **Strengths and limitations of this study**

- 2 • This study is among the first to investigate the evolution of cardiometabolic
3 multimorbidity and their risk of mortality in a general population under
4 real-world circumstances in China.
- 5 • We used longitudinal design with continuous surveillance on cardiometabolic
6 disease status in a general population to provide a better understanding of the
7 etiological association and causality in addition to using the multimorbidity
8 assessed only at baseline.
- 9 • The Chinese Electronic health Records Research in Yinzhou (CHERRY) study is a
10 large, natural population-based, observational cohort study linking big data of
11 integrated individual-level electronic health records (EHRs), with published
12 protocol on *BMJ open* 2018; 8(2): e019698.
- 13 • Although the CHERRY study has a relatively large number of participants, it is a
14 regional cohort located in a developed area of China and as such, will not be
15 nationally representative.
- 16 • This study has relatively short period of follow-up where long-term effect of
17 these cardiometabolic comorbidity will be further evaluated in the future.

18 INTRODUCTION

19 With the considerable improvement of medical intervention and healthcare management, the
20 aging of population has become one of the major concerns in public health worldwide.
21 Cardiometabolic comorbidity, defined herein as the co-existence of two or more of the
22 following cardiometabolic disorders: hypertension, diabetes mellitus, cardiovascular disease
23 (CVD), becomes progressively more common in the world and arises attention about their
24 impacts on public health during past several years.¹⁻³ The prevalence of each individual
25 disease is increasing rapidly along with significant changes in economic development and
26 lifestyle in China.⁴⁻⁷ Though a few studies evaluated the prevalence of multimorbidity based
27 on cross-sectional design in China,⁸⁻¹¹ they have been limited by small sample size, judged as
28 having a high risk of bias according to Strengthening the Reporting of Observational Studies
29 in Epidemiology (STROBE) guideline, restriction to only elder population (>60 years), or
30 included other chronic diseases (e.g. COPD or cancer) in the definition of multimorbidity.
31 Moreover, multimorbidity is in fact a continuum, covering the transitions from healthy status,
32 development of a single disease, and then progression to two or more multimorbidity with
33 the addition of further diseases.¹² The term of "evolution of multimorbidity" was proposed to
34 describe this whole process, which was generally required to be evaluated from a longitudinal
35 perspective. There were limited studies in this case. However, none of them was conducted in
36 Chinese populations.

37
38 On the other hand, many studies have shown that multimorbidity is associated with high risk
39 of mortality.¹³⁻¹⁵ Specifically, the Emerging Risk Factors Collaboration reported that mortality
40 was similarly associated with a history of diabetes, stroke or MI and multiplicative mortality
41 risk was observed for any combination of these conditions in Western population.¹⁶ However,
42 hypertension was not included in their evaluation. Time-varying exposure information to
43 update multimorbidity status was also not available in their study. Longitudinal design with
44 continuous surveillance on cardiometabolic disease status in a general population could
45 provide a better understanding of the etiological association and causality in addition to using
46 the multimorbidity assessed only at baseline.

1
2 47
3
4 48 Therefore, based on the Chinese Electronic Health Records Research in Yinzhou (CHERRY)
5
6 49 study, which is a longitudinal cohort study and consisted of 1,038,704 adults and 22,750
7
8 50 deaths during 2010 through 2016, we aimed to provide reliable estimates about prevalence
9
10 51 of cardiometabolic comorbidities, investigate the evolution of multimorbidity during follow-up,
11
12 52 and assess their association with mortality in a Chinese population.
13
14 53

15 54 **METHODS**

16 55 **Study Design**

17
18
19 56 The CHERRY study is a longitudinal population-based ambispective cohort study for
20
21 57 cardiovascular care and outcomes research by extracting individual participant data from
22
23 58 regional health information system of Yinzhou, an eastern coastal area of China. Detailed
24
25 59 description of this big data sources and cohort profile was published previously.¹⁷ Specific
26
27 60 data sources essential to this current study included: (1) the population census and
28
29 61 registered health insurance database for individuals' general demographic characteristics; (2)
30
31 62 health check databases including health checks from New Rural Cooperative Medical Scheme,
32
33 63 elder people and adults with hypertension and diabetes; (3) inpatient and outpatient
34
35 64 electronic medical records (EMRs); (4) disease surveillance and management database for
36
37 65 capturing the incidence of CVD, hypertension, diabetes where cases were required to be
38
39 66 reported for disease management by local general practitioners (GPs) once their diagnoses
40
41 67 were confirmed; (5) death certificates database where attribution of death refers to the
42
43 68 primary cause provided by cause-specific mortality.
44
45 69

46 70 All subjects were included in CHERRY study if they met all the following criteria: (1) over 18
47
48 71 years old on 1 January 2009; (2) have complete information on date of birth, sex, and a valid
49
50 72 healthcare identifier; (3) have been living in Yinzhou for at least 6 months, and (4) have
51
52 73 Chinese nationality. A total of 1,053,563 adults were originally enrolled in CHERRY study. In
53
54 74 this analysis, we choose 1 January 2010 as the date of inception to bypass the integration
55
56 75 and preliminary test period of the electronic health record (EHR) system and to allow for the

1
2 76 better coverage of the regional chronic disease management services. Overall, a total of
3
4 77 1,038,704 participants were included in current study after excluding subjects who died in
5
6 78 2009 or entered the system after 2016 (**eFigure 1**). Participants is generally continuously
7
8 79 followed up in the health information system and imported into CHERRY study annually from
9
10 80 the system. Complete follow-up data were available for participants through to 31th Dec
11
12 81 2016. This study was approved by the Peking University Institutional Review Board
13
14 82 (IRB00001052-16011).

15 83

17 84 **Cardiometabolic comorbidities and Outcome**

19 85 Cardiometabolic comorbidity was defined as the presence of two or more following diagnosed
20
21 86 disorders: hypertension, diabetes, or cardiovascular disease (CVD). We further categorized
22
23 87 participants into the following 8 groups: (1) hypertension, (2) diabetes, (3) CVD, (4)
24
25 88 hypertension and diabetes, (5) hypertension and CVD, (6) diabetes and CVD, (7)
26
27 89 hypertension, diabetes and CVD, and (8) none of these diseases as the reference group.
28
29 90 Diagnosis of these cardiometabolic diseases (and the date of diagnosis) were sought from
30
31 91 multiple sources: diseases management database (primary care), EMRs (hospital care), and
32
33 92 disease surveillance database (disease registry). Disease surveillance was considered as gold
34
35 93 standard for the date of diagnosis for diseases. Details of the comprehensive health care
36
37 94 services for chronic disease surveillance and management provided in this region was
38
39 95 described previously.¹⁷ Besides the baseline status of individuals' cardiometabolic diseases,
40
41 96 longitudinal information of the exposure was also used. In this case, in order to evaluate the
42
43 97 mortality association with a history of hypertension, diabetes, CVD and their cardiometabolic
44
45 98 comorbidities, the change of cardiometabolic disease status occurred no more than 30 days
46
47 99 before deaths was excluded, assuming that there was a direct connection between the
48
49 100 change of cardiometabolic comorbidity status and mortality within the acute phase. The
50
51 101 primary outcome was the all-cause mortality during the follow-up. Death was confirmed by
52
53 102 death certificate in the health information system, which have been described previously.¹⁸
54
55 103 Diseases and deaths were classified according to the International Classification of Diseases,
56
57 104 Tenth Revision (ICD-10).

105

106 Statistical Analysis

107 Age- and sex- standardized prevalence and 95% CIs of cardiometabolic comorbidity at
108 baseline and at the last visit were estimated in the overall population (and in population aged
109 40 years or older in the supplementary analysis) based on the distribution of the 2010
110 Chinese population census. 105,209 (10.1%) participants changed the cardiometabolic
111 comorbidity status during follow-up. Numbers the corresponding percentages of participants
112 who changed their cardiometabolic disease status within each 8 combination listed above
113 were summarized. Poisson regression model adjusted to sex was used to calculate mortality
114 rates adjusted to the age of 60 years. For the association of cardiometabolic multimorbidity
115 with mortality, we firstly assessed the associations of the cardiometabolic comorbidity groups
116 at baseline with risk of death from any cause. Furthermore, cardiometabolic comorbidity
117 status was modelled as a time dependent exposure to enable updating of multimorbidity
118 status during follow-up. The hazard ratios (HRs) were calculated using Cox proportional
119 hazard regression models stratified by sex and adjusted for age in the primary analysis in
120 overall population, population aged 40 years or older, and in subgroups of sex, age, location
121 (urban / rural), status of smoking, and categories of body mass index. Finally, population
122 attributable fractions (PAF) and 95% CI due to one, two or three cardiometabolic diseases
123 were estimated by combining the proportional excess mortality (X_1 , X_2 , and X_3 , where
124 $X=HR-1$) and standard error in each category with the corresponding prevalence at baseline
125 (P_1 , P_2 and P_3).¹⁹ The PAFs for one, two or ≥ 3 disorders are then P_1X_1/k , P_2X_2/k and P_3X_3/k ,
126 where $k=1 + P_1X_1 + P_2X_2 + P_3X_3$. PAFs were calculated based on 1) the prevalence and HRs
127 of cardiometabolic multimorbidity at baseline; 2) the prevalence at last visit and HRs using
128 time-variant cardiometabolic multimorbidity status. All p values were two-tailed and were not
129 adjusted for multiple testing. We judged p values less than 0.05 significant. We used Stata
130 (version 14.0) for all data analyses.

131

132 RESULTS

1
2 133 The current cohort was established through the procedures listed in the **supplementary**
3
4 134 **eFigure 1**. We began with 1.28 million permanent residents in Yinzhou, China with a valid
5
6 135 personal identifier. After excluding subjects younger than 18 years old on or died before
7
8 136 January 1 2010 and subjects entered the system after December 31 2016, we included
9
10 137 overall 1,038,704 participants aged 18 years or older from CHERRY study in the current
11
12 138 analyses. The baseline characteristics of the study participants were shown in **Table 1**. The
13
14 139 mean (SD) age at baseline was 42.5 (14.8) and 51.4% were women. The mean (SD) of BMI
15
16 140 was 22.5 (2.5) kg/m². According to Asian-specific cutoffs of BMI, 24.1% were overweight
17
18 141 ($23 \leq \text{BMI} < 25$ kg/m²) and 13.9% were obese ($\text{BMI} \geq 25$ kg/m²).
19
20 142

21 143 **Prevalence and Evolution of Cardiometabolic Comorbidity**

22
23 144 At baseline, among total 1,038,704 subjects aged 18 years or older, 85,684 participants had
24
25 145 a history of one diagnosed cardiometabolic disease, 22,871 participants had a history of two
26
27 146 diseases, and 2,203 participants had 3 diseases respectively. The corresponding
28
29 147 standardized prevalence were 9.32% (95% CI: 9.26%-9.37%), 2.57% (2.54%-2.60%) and
30
31 148 0.26% (0.25%-0.27%) respectively (**Table 2**). The estimated prevalence for the diagnosed
32
33 149 cardiometabolic comorbidity was generally increased along with age and higher in women
34
35 150 than men (**Figure 1**). Among the population aged 40 years or older, the standardized
36
37 151 prevalence were 16.82% (16.72%-16.92%) for one disease, 4.69% (4.65%-4.75%) for two
38
39 152 diseases and 0.47% (0.45%-0.49%) for three diseases respectively (**supplementary**
40
41 153 **eTable 1**). In the elderly population (aged 60 years or older), the corresponding prevalence
42
43 154 increased to 31.90% (31.65%-32.14%), 10.41% (10.25%-10.57%) and 1.20%
44
45 155 (1.14%-1.26%) respectively (**supplementary eTable 2**).
46
47 156

48 157 A total of 105,209 out of 1,038,704 individuals (10.1%) in the study changed their
49
50 158 cardiometabolic comorbidity status during median 5-year follow-up (**supplementary**
51
52 159 **eTable 3**). The prevalence of cardiometabolic multimorbidity increased from 2.41%
53
54 160 (2.38%-2.44%) to 5.94% (5.90%-5.99%) (**Figure 2**). The following four conditions with
55
56 161 total 72,104 (68.5%) subjects lead all the transitions: 47,903 and 8,388 subjects developed

1
2 162 hypertension or diabetes from healthy condition respectively, 9,279 patients with
3
4 163 hypertension and 6,534 patients with hypertension and diabetes further developed CVD.
5
6 164 Among 927,946 subjects without any diagnosed cardiometabolic disease at baseline, 73,302
7
8 165 (7.9%) developed one or more cardiometabolic diseases. 47,903 (5.2%) subjects developed
9
10 166 hypertension only. Among 85,684 subjects with only one disease at baseline, 24,041 (28.1%)
11
12 167 developed additional cardiometabolic diseases. Among all 69,406 patients with hypertension
13
14 168 at baseline, 12,711 (18.31%) patients had incidence of CVD during follow-up. Among all
15
16 169 14,127 patients with diabetes at baseline, 5,386 (38.13%) patients had incidence of CVD
17
18 170 during follow-up. Finally, overall 7,865 (34.39%) out of 22,871 patients with two
19
20 171 cardiometabolic diseases developed all three diagnosed diseases during follow-up. Patients
21
22 172 with all three diseases increase from 2,203 at baseline to 18,547 by the end of the study
23
24 173 **(supplementary eTable 3).**

25 174

26 175 **Association with mortality**

27
28 176 There were total 22,750 deaths during 5.43 million person-years follow-up (median follow-up
29
30 177 time, 5.16 years) in the study. Overall, the sex-adjusted all-cause mortality rate at the age of
31
32 178 60 years was 5.68 per 1000 person-years, with 6.50 in men and 4.91 in women. In the
33
34 179 analysis using baseline status of cardiometabolic comorbidity, compared with the participants
35
36 180 without any selected disease, the age- and sex-adjusted HRs (95% CIs) for mortality was
37
38 181 1.37 (1.33-1.42) in those with one disease, 1.71 (1.64-1.79) in those with two diseases, and
39
40 182 2.22 (2.00-2.46) in those with all three diseases (**Figure 3**). Among all the combinations of
41
42 183 cardiometabolic comorbidity, patients with either history of CVD only or diabetes and CVD
43
44 184 were highest, i.e. 3.31 (3.05-3.59) and 3.12 (2.37-4.11) respectively, whereas patients with
45
46 185 hypertension only had lowest HR as 1.26 (1.22-1.30). HRs for cardiometabolic comorbidity
47
48 186 were broadly similar in men vs. women, higher in younger participants (age<40 years), and
49
50 187 higher in subjects living in urban areas (supplementary eTable 4). Sensitivity analysis for the
51
52 188 analysis using baseline status excluding the initial 1 year of follow-up was broadly similar
53
54 189 **(supplementary eTable 5).**

55 190

1
2 191 In contrast, considering the longitudinal information of the cardiometabolic comorbidity,
3
4 192 compared with the participants without any selected disease at the last visit, the age- and
5
6 193 sex-adjusted HRs (95% CIs) for mortality was broadly similar as 1.36 (1.32-1.41) in those
7
8 194 with one disease, higher as 2.03 (1.96-2.10) in those with two diseases, and similar as 2.16
9
10 195 (2.05-2.29) in those with all three diseases (**Figure 3**). Though the pattern of HRs within
11
12 196 each combination of comorbidity were broadly similar as the analysis using baseline status,
13
14 197 the HR in patients with only hypertension reduced to 1.07 (1.03-1.10), whereas patients with
15
16 198 history of CVD increased to 4.80 (4.55-5.07). Moreover, the HR in patients with hypertension
17
18 199 and diabetes was attenuated to 1.30 (1.22-1.39), whereas patients with hypertension and
19
20 200 history of CVD increased to 2.36 (2.27-2.45).

201

202 **Population Attributable Fractions**

203 Using the prevalence and HRs of cardiometabolic disease status at baseline, the population
204 attributable fractions for all-cause mortality due to one cardiometabolic disease, two diseases
205 and three diseases were 3.30% (2.95%-3.65%), 1.73% (1.56%-1.90%) and 0.30%
206 (0.25%-0.36%) in the overall population aged 18 years or older (**Table 3**). In people aged 40
207 years old, PAF increased to 5.10% (4.52%-5.68%), 2.85% (2.56%-3.14%) and 0.50%
208 (0.40%-0.59%) respectively. Using the prevalence at last visit and HRs using time-variant
209 cardiometabolic disease status, PAFs due to one, two or three diseases were 4.17%
210 (3.70%-4.63%), 4.36% (4.07%-4.65%) and 2.13% (1.92%-2.35%). The overall PAF
211 increased from 5.34% (4.96%-5.72%) to 10.66% (10.11%-11.21%).

212

213 **DISCUSSION**

214 Our analyses of more than 1 million Chinese adults with 22,750 deaths occurred during
215 follow-up in a longitudinal cohort has provided estimates of the prevalence of cardiometabolic
216 comorbidity (i.e. hypertension, diabetes, and/or history of CVD) in a general population
217 under real-world circumstances, investigate the evolution of cardiometabolic diseases in this
218 population within 5-year of follow-up, and evaluated its association with risk of all-cause
219 mortality. Each of our main findings has potential implications.

1
2 220
3

4 221 First, it was estimated that 12.2% of Chinese adults aged 18 years or older in a real-world
5
6 222 general population have at least one diagnosed cardiometabolic disease and nearly 3% had
7
8 223 cardiometabolic multimorbidity. Patients with hypertension dominates the patients with any
9
10 224 selected disease. The prevalence of multimorbidity at baseline increased with age, which
11
12 225 increased to 5.2% in the population aged 40 years or older and 11.6% in the population aged
13
14 226 60 years or older. Among all patients with any cardiometabolic disease, one in four had
15
16 227 multimorbidity. This proportion was consistent in different age populations. Moreover, during
17
18 228 the median of 5-year follow-up, the proportion of patients having multimorbidity was more
19
20 229 than doubled. Strikingly, the proportion of patients had all three diseases in the original
21
22 230 population were nine-fold than the baseline prevalence (0.2% to 1.8%). Nearly 60% of
23
24 231 patients with both hypertension and diabetes at baseline had incidence of CVD during
25
26 232 follow-up. Over 30% of patients having diabetes or 20% of patients with hypertension
27
28 233 developed cardiometabolic comorbidity. These all indicated the surprisingly fast speed of the
29
30 234 progression of cardiometabolic diseases.

31 235

32 236 There were limited publications on the epidemiology of multimorbidity in a general Chinese
33
34 237 population. Most of them included other morbidities besides cardiometabolic diseases and
35
36 238 only prevalence based on numbers of diseases were reported, which prevent us for the direct
37
38 239 comparison. It is noted that the estimated prevalence of the single diagnosed disease was
39
40 240 broadly consistent with those estimated from the national surveillance. For example, though
41
42 241 the estimation of prevalence of diabetes in China reached 10.9% in 2013, the national
43
44 242 prevalence of diagnosed diabetes was only 4%.⁴ Because our population located in the
45
46 243 developed area of China, our estimation of 3% is considered as consistent as the prevalence
47
48 244 in this region is lower than the national estimation even in the traditional epidemiological
49
50 245 survey.

51 246

52
53 247 Secondly, we observed about one-third increased risk in patients who had only 1 condition
54
55 248 that we investigated at baseline, two-thirds higher risk in patients who had a combination of

1
2 249 any 2 diseases, and just over two-fold in patients who had all 3 conditions at baseline within
3
4 250 5-year of follow-up. Though these results appear to suggest that the association of
5
6 251 hypertension, diabetes and cardiovascular disease with mortality were additive in this
7
8 252 population, we found that there were significant heterogeneities within each combination of
9
10 253 disease conditions. Patients with only hypertension at baseline has lowest HR of 1.26 and
11
12 254 patients with CVD only at baseline had HR of 3.31. This pattern had been aggravated by
13
14 255 applying longitudinal information of the cardiometabolic disease status. Patients with only
15
16 256 hypertension reduced to 1.07 and patients with only CVD increased to 4.8. Within nearly
17
18 257 70,000 patients with hypertension at baseline, 15,000 of them developed additional
19
20 258 cardiometabolic diseases and therefore changed the category of disease status. In addition,
21
22 259 there were around 100,000 (10%) patients with hypertension at last in the study, nearly half
23
24 260 of them were identified during follow-up, i.e. suggested that they were newly diagnosed.
25
26 261 Therefore, using longitudinal information on disease status, patients with hypertension had
27
28 262 lower HR than those using baseline status. In contrast, there were small number of patients
29
30 263 (just over 2,000) at CVD only at baseline. Most of patients with history of CVD were
31
32 264 accompanied by either diabetes or hypertension. Around 4,000 patients developed CVD
33
34 265 during follow-up from healthy condition at baseline. We speculated that the increment of HR
35
36 266 from 3.3 using baseline status to 4.8 using longitudinal data may be partly due to the relative
37
38 267 short-term high risk after the first-ever CVD events. Similarly, we have also found the
39
40 268 increased risk for patient group with hypertension and CVD from the analysis using baseline
41
42 269 status to longitudinal definition of disease status.

43 270

44 271 In addition, regardless of the existence of other disease condition, history of CVD tends to
45
46 272 dominate the risk especially within 5 years of follow-up. Among patients with any
47
48 273 cardiometabolic diseases, patients with only history of CVD had highest risk, which may be
49
50 274 short-term effect of newly diagnosed CVD. Alternatively, it may also indicate that patients
51
52 275 with other cardiometabolic diseases, especially hypertension and/or diabetes, were likely to
53
54 276 be more aware of their health condition. Moreover, within the group of cardiometabolic
55
56 277 multimorbidity, only patients with hypertension and diabetes had significantly lower HR,

1
2 278 whereas other groups, i.e. all with CVD, were broadly similar, even in patients with all three
3
4 279 conditions. In the results from the Emerging Risk Factor Collaboration (ERFC) of 91 cohort
5
6 280 studies mainly from western population, they estimated that HR for mortality was about 2 in
7
8 281 participants with one condition of cardiometabolic multimorbidity (type 2 diabetes, coronary
9
10 282 heart diseases, and stroke) and the association was multiplicative.¹⁶ They didn't include
11
12 283 hypertension and used only baseline status of disease condition. We have seen that the
13
14 284 broadly similar HR was found for patients with diabetes. Higher HR was estimated in our
15
16 285 population for patients with CVD (stroke or MI) which may also be affected by the overall
17
18 286 healthcare service across countries with different economic levels. The estimated HR for
19
20 287 patients with CVD and diabetes (regardless of hypertension) was around 2.5, lower than the
21
22 288 estimation from ERFC (around 3.5-4) but consistent with the Hispanic Established Population
23
24 289 for the Epidemiological study of the Elderly (HR=2.4).²⁰ This may imply that the ethnic
25
26 290 disparity could be one of the reasons. The present study also showed that cardiometabolic
27
28 291 multimorbidity had more serious impact on population living in urban than in rural. It is
29
30 292 important to take location difference in the consideration for making strategies to improve
31
32 293 public health.

33 294

34 295 The strength and potential limitations of this investigation merit consideration. It is a large
35
36 296 and comprehensive study under real-world circumstances. Especially, we took the
37
38 297 longitudinal data of the cardiometabolic disease status to assess the prevalence and
39
40 298 evolution of cardiometabolic multimorbidity during follow-up. However, the study also has
41
42 299 several limitations. First, CHERRY study is based on a regional population in the developed
43
44 300 area of China, which is not nationally representative. Secondly, this study has relatively short
45
46 301 period of follow-up where long-term effect of these cardiometabolic comorbidity will be
47
48 302 further evaluated in the future. Thirdly, the accurate time of onset for the diseases, especially
49
50 303 hypertension and diabetes, were not available. We can only approximate this information by
51
52 304 the first diagnose time of these chronic diseases. Finally, our laboratory data sources included
53
54 305 the lipids measurements only in approximately 25% to 30% of the population, which prevent
55
56 306 us from the model adjustment of conventional lipids risk factors. However, in the results

1
2 307 shown by ERFC, broadly similar HRs of cardiometabolic multimorbidity with mortality were
3
4 308 observed after further adjustment of smoking, BMI, systolic blood pressure, high-density
5
6 309 lipoprotein and total cholesterol, socioeconomic status and diet.
7

8 310

9
10 311 **Conclusions**

11 312 The prevalence of patients having cardiometabolic comorbidity in a general population was
12
13 313 more than doubled within 5 years, indicating rapid evolution of cardiometabolic
14
15 314 multimorbidity in Chinese. Among all combinations, history of CVD leads the risk with
16
17 315 mortality. Our findings highlight the need for a complementary strategy for primary and
18
19 316 secondary prevention of cardiometabolic diseases in China.

STROBE 2007 (v4) Statement—Checklist of items that should be included in reports of *cohort studies*

Section/Topic	Item #	Recommendation	Reported on page #
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	1, 2
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4-5
Objectives	3	State specific objectives, including any prespecified hypotheses	5
Methods			
Study design	4	Present key elements of study design early in the paper	5-6
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	5-6
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up	5-6
		(b) For matched studies, give matching criteria and number of exposed and unexposed	Not applied
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	6
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	5-6
Bias	9	Describe any efforts to address potential sources of bias	6-7
Study size	10	Explain how the study size was arrived at	5, eFigure 1
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	6-7
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	7
		(b) Describe any methods used to examine subgroups and interactions	7
		(c) Explain how missing data were addressed	7
		(d) If applicable, explain how loss to follow-up was addressed	6
		(e) Describe any sensitivity analyses	7
Results			

Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	8, eFigure 1
		(b) Give reasons for non-participation at each stage	eFigure 1
		(c) Consider use of a flow diagram	eFigure 1
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	Table 1
		(b) Indicate number of participants with missing data for each variable of interest	eFigure 1
		(c) Summarise follow-up time (eg, average and total amount)	9
Outcome data	15*	Report numbers of outcome events or summary measures over time	9
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	Figure 3, eTable 4, 5
		(b) Report category boundaries when continuous variables were categorized	eTable 4, 5
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	9
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	eTable 4, 5
Discussion			
Key results	18	Summarise key results with reference to study objectives	10-14
Limitations			
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	3, 13-14
Generalisability	21	Discuss the generalisability (external validity) of the study results	3, 13
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	15

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at www.strobe-statement.org.

Abstract

Objectives: The evolution of multimorbidity describes the continuum from a healthy status to development of a single disease and further progression to multimorbidity with additional diseases. We investigated the evolution of cardiometabolic multimorbidity and risk for mortality in a Chinese population.

Design: Longitudinal cohort study using data from the CHinese Electronic health Records Research in Yinzhou (CHERRY) study, with 5.43 million person-years follow-up (median 5.16 years).

Participants: Data for 1,038,704 adults (total 22,750 deaths) were analyzed.

Exposure: Cardiometabolic multimorbidity was defined as ever being diagnosed with two or more of three diseases: hypertension, diabetes, and cardiovascular disease (CVD).

Primary and secondary outcome measures: Age- and sex-adjusted hazard ratios (HRs) were calculated for all-cause mortality.

Results: The cardiometabolic disease status of 105,209 (10.1%) individuals changed during follow-up. The prevalence of cardiometabolic multimorbidity increased from 2.41% (95% confidence interval [CI]: 2.38%–2.44%) to 5.94% (95% CI: 5.90%–5.99%). Baseline multimorbidity status showed the HR (95% CI) was 1.37 (1.33–1.42) in those with one disease, 1.71 (1.64–1.79) in those with two diseases, and 2.22 (2.00–2.46) in those with three diseases. The highest HRs were observed for CVD only (3.31, 95% CI: 3.05–3.59) or diabetes and CVD (3.12, 95% CI: 2.37–4.11). Those with hypertension only had the lowest HR (1.26, 95% CI: 1.22–1.30). Longitudinal data showed the HRs (95% CI) in patients with one, two, and three diseases were 1.36 (1.32–1.41), 2.03 (1.96–2.10), and 2.16 (2.05–2.29), respectively.

Conclusions: The prevalence of cardiometabolic multimorbidity in a general Chinese population more than doubled over 5 years, indicating rapid evolution of

1
2
3 cardiometabolic multimorbidity. A history of CVD dominates the risk for mortality.
4
5 A complementary strategy for primary and secondary prevention of cardiometabolic
6
7 diseases is needed in China.

1 **Strengths and limitations of this study**

- 2 • This study is among the first to investigate the evolution of cardiometabolic
3 multimorbidity and risk for mortality in a general population in China.
- 4 • We used a longitudinal design with continuous surveillance of cardiometabolic
5 disease status to provide a better understanding of etiological associations
6 and causality, in addition to using multimorbidity assessed only at baseline.
- 7 • The Chinese Electronic health Records Research in Yinzhou (CHERRY) study is
8 a large-scale natural population-based observational cohort study linking
9 large data from integrated individual-level electronic health records, the
10 study protocol of which was published in *BMJ Open* 2018; 8(2): e019698.
- 11 • The CHERRY study involves a regional cohort located in a developed area of
12 China, and is therefore not nationally representative.
- 13 • This study had relatively short follow-up period.

14 INTRODUCTION

15 Considerable improvements in medical interventions and healthcare management mean
16 population aging has become a major public health concern worldwide. Cardiometabolic
17 multimorbidity is defined as the co-existence of two or more of three cardiometabolic
18 disorders: hypertension, diabetes mellitus, and cardiovascular disease (CVD).
19 Cardiometabolic multimorbidity is becoming progressively more common globally, and the
20 public health impact has received increased attention during the past several years.¹⁻³ The
21 individual prevalence of each disease is increasing rapidly in China, along with significant
22 changes in economic development and lifestyles.⁴⁻⁷ Although some studies have evaluated
23 the prevalence of multimorbidity in China using cross-sectional designs,⁸⁻¹¹ they have been
24 limited by factors such as: small sample sizes, high risk of bias according to the
25 Strengthening the Reporting of Observational Studies in Epidemiology guideline, restriction
26 to older adult populations (>60 years), or including other chronic diseases (e.g., chronic
27 obstructive pulmonary disease or cancer) in the definition of multimorbidity. Moreover,
28 multimorbidity is a continuum, covering the transition from healthy status to development
29 of a single disease and then progression to two or more diseases, with the possible addition
30 of further diseases.¹² The term "evolution of multimorbidity" describes this process, which
31 is generally evaluated from a longitudinal perspective. However, there have been limited
32 studies on this topic, and none conducted among Chinese populations.

33
34 Multimorbidity is associated with high risk for mortality.¹³⁻¹⁵ The Emerging Risk Factors
35 Collaboration (ERFC) reported that mortality was similarly associated with a history of
36 diabetes, stroke, or myocardial infarction (MI), and a multiplicative mortality risk was
37 observed for any combination of these conditions in Western populations.¹⁶ However,
38 hypertension was not included in that evaluation, and time-varying exposure information to
39 update multimorbidity status was not available. A study using a longitudinal design with
40 continuous surveillance of cardiometabolic disease status in a general population in addition
41 to using multimorbidity assessed at baseline may provide a better understanding of
42 etiological associations and causality.

1
2
3 43
4 44 The CHinese Electronic Health Records Research in Yinzhou (CHERRY) study is a longitudinal
5 45 cohort study involving 1,038,704 adults (22,750 deaths) from 2010 through 2016. Using
6 46 CHERRY data, we aimed to provide reliable estimates about the prevalence of
7 47 cardiometabolic comorbidities, investigate the evolution of multimorbidity during follow-up,
8 48 and assess the association with mortality in a Chinese population.

17 50 **METHODS**

18 51 **Study design**

19 52 The CHERRY study is a longitudinal population-based ambispective cohort study focused on
20 53 cardiovascular care and outcomes research. Individual participant data were extracted from
21 54 the regional health information system in Yinzhou, an eastern coastal area of China. A
22 55 detailed description of the data sources and cohort profile was published previously.¹⁷
23 56 Specific data sources essential to the present study included: 1) the population census and
24 57 registered health insurance database for individuals' general demographic characteristics;
25 58 2) health check databases, including health checks from the New Rural Cooperative Medical
26 59 Scheme, older adults, and adults with hypertension and diabetes; 3) inpatient and
27 60 outpatient electronic medical records (EMRs); 4) disease surveillance and management
28 61 database that captured the incidence of CVD, hypertension, and diabetes (where cases were
29 62 required to be reported for disease management by local general practitioners on
30 63 confirmation of diagnosis); and 5) death certificates database where attribution of death
31 64 refers to the primary cause provided by cause-specific mortality.

41
42
43
44
45
46
47
48

49 66 Individuals were included in the CHERRY study if they met all inclusion criteria: 1) aged ≥ 18
50 67 years on 1 January 2009; 2) had complete information on date of birth, sex, and a valid
51 68 healthcare identifier; 3) had been living in Yinzhou for at least 6 months; and 4) had Chinese
52 69 nationality. In total, 1,053,563 adults were originally enrolled in the CHERRY study. In this
53 70 analysis, we choose 1 January 2010 as the date of inception to bypass the integration and
54 71 preliminary test period of the EMR system and allow for better coverage of regional chronic
55
56
57
58
59
60

1
2
3 72 disease management services. After excluding those who died in 2009 or entered the system
4
5 73 after 2016, we included 1,038,704 participants in this study (**Supplementary eFigure 1**).
6
7 74 Follow-up in the health information system is generally continuous. CHERRY updates
8
9 75 information for all cohort members annually from the health information system databases.
10
11 76 Complete follow-up data were available for participants through to December 31, 2016. This
12
13 77 study was approved by the Peking University Institutional Review Board (IRB00001052-
14
15 78 16011).

16
17 79

18 80 **Cardiometabolic multimorbidities and outcomes**

19
20 81 Cardiometabolic multimorbidity was defined as the presence of two or more of three
21
22 82 diagnosed disorders: hypertension, diabetes, or CVD [including coronary heart disease (CHD)
23
24 83 and cerebrovascular diseases]. We categorized participants into eight groups: 1)
25
26 84 hypertension, 2) diabetes, 3) CVD, 4) hypertension and diabetes, 5) hypertension and CVD,
27
28 85 6) diabetes and CVD, 7) hypertension, diabetes, and CVD, and 8) none of these diseases
29
30 86 (reference group). Diagnosis of these cardiometabolic diseases (and date of diagnosis) were
31
32 87 obtained from multiple sources: diseases management database (primary care), EMRs
33
34 88 (hospital care), and disease surveillance database (disease registry). Date in disease
35
36 89 surveillance was considered the gold standard for the date of diagnosis. Details of the
37
38 90 comprehensive healthcare services for chronic disease surveillance and management
39
40 91 provided in the study region were described previously.¹⁷ In addition to individuals' baseline
41
42 92 cardiometabolic disease status, longitudinal information for the exposure was also used. To
43
44 93 evaluate the association between mortality and a history of hypertension, diabetes, CVD,
45
46 94 and their cardiometabolic multimorbidities, changes in cardiometabolic disease status that
47
48 95 occurred ≤ 30 days before death were excluded, assuming that there was a direct connection
49
50 96 between the change of cardiometabolic multimorbidity status and mortality within the acute
51
52 97 phase. The primary outcome was all-cause mortality during follow-up. Death was confirmed
53
54 98 by the death certificate in the health information system, as previously described.¹⁸ Diseases
55
56 99 and deaths were classified according to the International Classification of Diseases, Tenth
57
58 100 Revision (ICD-10).

1
2
3 101
4
5 102 **Statistical analysis**
6
7 103 Continuous and categorical baseline characteristics of participants were summarized by
8
9 104 mean [standard deviation (SD)] or numbers (percentage) respectively. Cardiometabolic
10
11 105 multimorbidities were classified as 8 combinations listed above. Numbers (and
12
13 106 corresponding percentages) of participants who changed their cardiometabolic disease
14
15 107 status during follow-up were summarized. Age- and sex- standardized prevalence and 95%
16
17 108 confidence intervals (CI) for cardiometabolic multimorbidity at baseline and at the last visit
18
19 109 were estimated for the overall population (and the population aged ≥ 40 years in a
20
21 110 supplementary analysis) based on the distribution of the 2010 Chinese population census.
22
23 111 A Poisson regression model adjusted for sex was used to calculate mortality rates, adjusted
24
25 112 for age 60 years. To investigate the association between cardiometabolic multimorbidity and
26
27 113 mortality, we first assessed the associations between the cardiometabolic multimorbidity
28
29 114 groups at baseline and risk for death from any cause. Furthermore, cardiometabolic
30
31 115 multimorbidity status was modeled as a time dependent exposure to enable updating of
32
33 116 multimorbidity status during follow-up. Hazard ratios (HRs) and 95% CIs were calculated
34
35 117 using Cox proportional hazard regression models stratified by sex and adjusted for age in
36
37 118 the primary analyses of the overall population, the population aged ≥ 40 years, and
38
39 119 subgroups (sex, age, location [urban/rural], smoking status, and body mass index [BMI]
40
41 120 category). To explore the extent to which conventional factors (BMI, smoking, education
42
43 121 level, and location) explained the associations between cardiometabolic multimorbidity and
44
45 122 mortality, HRs adjusted for these additional factors were calculated for people with full
46
47 123 information on these factors. Finally, population attributable fractions (PAF) and 95% CI due
48
49 124 to one, two or three cardiometabolic diseases were estimated by combining the proportional
50
51 125 excess mortality (X_1 , X_2 , and X_3 ; where $X=HR-1$) and standard error in each category with
52
53 126 the corresponding prevalence at baseline (P_1 , P_2 , and P_3).¹⁹ The PAFs for one, two, or three
54
55 127 disorders are P_1X_1/k , P_2X_2/k , and P_3X_3/k ; where $k=1 + P_1X_1 + P_2X_2 + P_3X_3$. PAFs were
56
57 128 calculated based on: 1) the prevalence and HRs of cardiometabolic multimorbidity at
58
59 129 baseline; and 2) the prevalence at last visit and HRs using time-variant cardiometabolic

1
2
3 130 multimorbidity status. All p-values were two-tailed and not adjusted for multiple testing. We
4
5 131 used Stata (version 14.0) for all data analyses, with a statistical significance level of $P <$
6
7 132 0.05.

8
9 133

10 134 **Patient and public involvement**

11
12 135 Patients were not involved in the development of the research question or measures, or the
13
14 136 design, recruitment, or conduct of this study. The results of this study will be disseminated
15
16 137 to study participants and the public via this publication and the CHERRY study website
17
18 138 (<http://www.cherry-study.org>).

19
20
21 139

22 140 **RESULTS**

23
24 141 The present cohort was established using the procedures listed in **Supplementary eFigure**
25
26 142 **1**. We began with 1.28 million permanent residents in Yinzhou, China with a valid personal
27
28 143 identifier. After excluding subjects younger than 18 years old as at January 1, 2010, those
29
30 144 that died before that date, and those entered into the system after December 31, 2016, the
31
32 145 present analyses included 1,038,704 CHERRY study participants aged ≥ 18 years. **Table 1**
33
34 146 shows participants' baseline characteristics. Among all participants, 1,025,542 (98.7%) had
35
36 147 information on living location, 858,413 (82.6%) had information on education level, 905,987
37
38 148 (87.2%) had at least one BMI measurement, and 905,987 (88.7%) had at least one smoking
39
40 149 status measurement. The mean \pm SD age at baseline was 42.5 ± 14.8 years (51.4% women).
41
42 150 The mean BMI was 22.5 ± 2.5 kg/m². According to Asian-specific BMI cutoffs, 24.1% were
43
44 151 overweight (23–25 kg/m²) and 13.9% were obese (BMI ≥ 25 kg/m²). At the last visit during
45
46 152 follow-up, the mean BMI was 22.5 ± 2.6 kg/m²; 23.9% were overweight and 14.8% were
47
48 153 obese. From baseline to the last visit, the proportion of former smokers changed from 2.2%
49
50 154 to 2.4% and the proportion of current smokers changed from 18.9% to 20.0%.

51
52
53 155

54 156 **Prevalence and evolution of cardiometabolic multimorbidity**

55
56 157 At baseline, 85,684 participants had one diagnosed cardiometabolic disease, 22,871 had
57
58 158 two diseases, and 2,203 had three diseases. The standardized prevalence were 9.32% (95%
59
60

1
2
3 159 CI: 9.26%–9.37%) for one disease, 2.57% (95% CI: 2.54%–2.60%) for two diseases, and
4
5 160 0.26% (95% CI: 0.25%–0.27%) for three diseases (**Table 2**). The estimated prevalence of
6
7 161 diagnosed cardiometabolic multimorbidity increased with age and was higher in women than
8
9 162 men (**Figure 1**). Among the population aged ≥ 40 years, the standardized prevalence rates
10
11 163 were 16.82% (95% CI: 16.72%–16.92%) for one disease, 4.69% (95% CI: 4.65%–4.75%)
12
13 164 for two diseases, and 0.47% (95% CI: 0.45%–0.49%) for three diseases (**Supplementary**
14
15 165 **eTable 1**). In the population aged ≥ 60 years, the prevalence rates increased to 31.90%
16
17 166 (95% CI: 31.65%–32.14%), 10.41% (95% CI: 10.25%–10.57%), and 1.20% (95% CI:
18
19 167 1.14%–1.26%) for one, two, and three diseases, respectively (**Supplementary eTable 2**).
20
21 168
22
23 169 In total, 105,209 participants (10.1%) changed their cardiometabolic multimorbidity status
24
25 170 during the (median) 5-year follow-up (**Supplementary eTable 3**). Regarding the history
26
27 171 of CVD, 50,458 (94.4%) of all 53,473 patients have information on type of CVD. Within
28
29 172 these patients, 26,282 had CHD, 23,538 had cerebrovascular diseases and 638 had both
30
31 173 CHD and cerebrovascular diseases respectively. The crude prevalence of cardiometabolic
32
33 174 multimorbidity increased from 2.41% (95% CI: 2.38%–2.44%) to 5.94% (95% CI: 5.90%–
34
35 175 5.99%) (**Figure 2 & Supplementary eTable 3**). Four disease groups (72,104 participants;
36
37 176 68.5%) lead all transitions during follow-up: 47,903 healthy subjects developed
38
39 177 hypertension only; 8,388 healthy subjects developed diabetes only; 9,279 patients with
40
41 178 hypertension developed CVD; and 6,534 patients with hypertension and diabetes developed
42
43 179 CVD. Among 927,946 participants without any diagnosed cardiometabolic disease at
44
45 180 baseline, 73,302 (7.9%) developed one or more cardiometabolic diseases, of which 47,903
46
47 181 (5.2%) developed hypertension only. Among 85,684 participants with one disease at
48
49 182 baseline, 24,041 (28.1%) developed additional diseases. Of 69,406 participants with
50
51 183 hypertension at baseline, 12,711 (18.31%) had an incidence of CVD during follow-up. Of
52
53 184 14,127 participants with diabetes at baseline, 5,386 (38.13%) had an incidence of CVD
54
55 185 during follow-up. Finally, 7,865 (34.39%) of 22,871 participants with two diseases
56
57 186 developed all three diseases during follow-up. The number of participants with all three
58
59
60

187 diseases increased from 2,203 at baseline to 18,547 by the end of the study
188 **(Supplementary eTable 3).**

189

190 **Associations with mortality**

191 There were 22,750 deaths during the 5.43 million person-years of follow-up (median follow-
192 up time, 5.16 years). The sex-adjusted all-cause mortality rate at age 60 years was 5.68
193 per 1000 person-years (6.50 in men, 4.91 in women). In the analysis using baseline
194 cardiometabolic multimorbidity status, the age- and sex-adjusted HRs for mortality were
195 1.37 (95% CI: 1.33–1.42) for one disease, 1.71 (95% CI: 1.64–1.79) for two diseases, and
196 2.22 (95% CI: 2.00–2.46) for three diseases, compared with participants without any
197 disease **(Figure 3)**. The highest HRs were observed in patients with either a history of CVD
198 only (3.31, 95% CI: 3.05–3.59) or diabetes and CVD (3.12, 95% CI: 2.37–4.11). Patients
199 with hypertension only had lowest HR (1.26, 95% CI: 1.22–1.30). HRs for cardiometabolic
200 multimorbidity were broadly similar in men and women, higher in younger participants (aged
201 <40 years), and higher in those living in urban areas **(Supplementary eTable 4)**. The
202 sensitivity analysis for the analysis using baseline status excluding the initial 1 year of follow-
203 up was broadly similar **(Supplementary eTable 5)**.

204

205 The longitudinal data for cardiometabolic multimorbidity showed the age- and sex-adjusted
206 HRs for mortality were broadly similar in those with one disease (1.36, 95% CI 1.32–1.41),
207 higher in those with two diseases (2.03, 95% CI 1.96–2.10), and similar in those with all
208 three diseases (2.16, 95% CI 2.05–2.29) compared with participants without any disease
209 at the last visit **(Figure 3)**. Although the pattern of HRs within each multimorbidity
210 combination were broadly similar to the analysis using baseline status, the HR in participants
211 with hypertension only reduced to 1.07 (95% CI 1.03–1.10), whereas that for those with
212 history of CVD increased to 4.80 (95% CI 4.55–5.07). The HR in those with hypertension
213 and diabetes was attenuated to 1.30 (95% CI 1.22–1.39), whereas that for participants with
214 hypertension and CVD increased to 2.36 (95% CI 2.27–2.45). Broadly similar association
215 were observed among the 788,703 participants with full information on additional risk

216 factors (BMI, smoking, education level and location) after further adjustment for those
217 factors (**Supplementary eTable 6**).

218

219 **PAFs**

220 Using the prevalence and HRs for cardiometabolic disease status at baseline, the PAFs for
221 all-cause mortality in the overall population aged ≥ 18 years due to one, two, and three
222 cardiometabolic diseases were 3.30% (95% CI: 2.95%–3.65%), 1.73% (95% CI: 1.56%–
223 1.90%), and 0.30% (95% CI: 0.25%–0.36%), respectively (**Table 3**). In people aged ≥ 40
224 years, the PAF increased to 5.10% (95% CI: 4.52%–5.68%) for one disease, 2.85% (95%
225 CI: 2.56%–3.14%) for two diseases, and 0.50% (95% CI: 0.40%–0.59%) for three diseases.
226 Using the prevalence at last visit and HRs for time-variant cardiometabolic disease status,
227 PAFs were 4.17% (95% CI: 3.70%–4.63%) for one disease, 4.36% (95% CI: 4.07%–4.65%)
228 for two diseases, and 2.13% (95% CI: 1.92%–2.35%) for three diseases. The overall PAF
229 increased from 5.34% (95% CI: 4.96%–5.72%) to 10.66% (95% CI: 10.11%–11.21%).

230

231 **DISCUSSION**

232 Our analyses of more than 1 million Chinese adults (22,750 deaths during follow-up) in a
233 longitudinal cohort provided estimates of the prevalence of cardiometabolic multimorbidity
234 (hypertension, diabetes, and CVD) in a general population under real-world circumstances.
235 This study also described the evolution of cardiometabolic diseases in this population over 5
236 years and evaluated associations with risk for all-cause mortality. Each of our main findings
237 has potential implications.

238

239 First, 12.2% of Chinese adults aged ≥ 18 years in a real-world general population had at
240 least one diagnosed cardiometabolic disease, and nearly 3% had cardiometabolic
241 multimorbidity. Hypertension was the dominant diagnosis in the group with one disease.
242 The prevalence of multimorbidity at baseline increased with age, and was 5.2% in the
243 population aged ≥ 40 years and 11.6% in the population aged ≥ 60 . One in four patients with
244 any cardiometabolic disease had multimorbidity. This proportion was consistent in different

1
2
3 245 age groups. Moreover, the proportion of patients with multimorbidity more than doubled
4
5 246 during the (median) 5-year follow-up. The proportion of patients with all three diseases
6
7 247 increased to nine-fold the baseline prevalence (0.2% to 1.8%). Nearly 60% of patients with
8
9 248 both hypertension and diabetes at baseline had an incidence of CVD during follow-up. Over
10
11 249 30% of patients with diabetes and 20% of patients with hypertension developed
12
13 250 cardiometabolic multimorbidity. These findings highlighted the rapid progression of
14
15 251 cardiometabolic diseases.

16
17 252
18
19 253 Limited publications are available on the epidemiology of multimorbidity in a general Chinese
20
21 254 population. A systematic review of nine published studies in China reported the prevalence
22
23 255 of multimorbidity among those aged ≥ 60 years ranged from 6.4% (95% CI: 5.1–8.0) to
24
25 256 76.5% (95% CI: 73.6–79.2).¹⁰ However, most of the included studies considered morbidities
26
27 257 in addition to cardiometabolic diseases and only reported prevalence based on number of
28
29 258 diseases, which prevented us making direct comparisons. The estimated prevalence of single
30
31 259 diagnosed diseases in our study was broadly consistent with estimates from national
32
33 260 surveillance. For example, although the estimate of the prevalence of diabetes in China
34
35 261 reached 10.9% in 2013, the national prevalence of diagnosed diabetes was only 4%.⁴
36
37 262 Because our population was located in a developed area of China, our estimate of 3% is
38
39 263 consistent with expectations, as the prevalence in this region is lower than the national
40
41 264 estimate, even in traditional epidemiological surveys. Compared with developed countries,
42
43 265 about 0.52% of participants aged ≥ 40 years (mean age 53.6 ± 11.6 years) in our cohort had
44
45 266 multimorbidity of diabetes and CVD (regardless of hypertension, $0.47\% + 0.05\% = 0.52\%$,
46
47 267 **eTable 1**), which was similar as 0.7% reported in the UK Biobank (mean age 56.7 ± 8.1
48
49 268 years).¹⁶ About 1.3% of participants aged ≥ 60 years in our cohort had multimorbidity of
50
51 269 diabetes and CVD, compared with 5% from a recent US survey involving people aged ≥ 65
52
53 270 years.²⁰ Previous studies in China and other countries have also shown that the prevalence
54
55 271 of multimorbidity increased significantly with age.^{9, 21} Older adults should therefore be a
56
57 272 major population targeted for cardiometabolic multimorbidity prevention, considering
58
59 273 population aging.

1
2
3 274
4
5 275 Second, over the 5-year follow-up we observed about a one-third higher mortality risk in
6
7 276 patients with one condition at baseline, a two-thirds higher risk in patients with two diseases,
8
9 277 and just over a two-fold higher risk in patients with all three diseases. Although these results
10
11 278 may suggest that associations between mortality and hypertension, diabetes, and
12
13 279 cardiovascular disease were additive in this population, we found significant heterogeneities
14
15 280 within each disease combination. Patients with only hypertension at baseline had the lowest
16
17 281 HR (1.26) and those with CVD only at baseline had a HR of 3.31. This pattern was aggravated
18
19 282 by applying longitudinal cardiometabolic disease status information. The HR of patients with
20
21 283 hypertension only reduced to 1.07 and that of patients with CVD only increased to 4.8.
22
23 284 Among around 70,000 patients with hypertension at baseline, 15,000 developed additional
24
25 285 cardiometabolic diseases, and therefore changed their disease status category. In addition,
26
27 286 there were around 100,000 (10%) patients with hypertension in this study, and nearly half
28
29 287 were identified during follow-up (i.e., suggesting that they were newly diagnosed). Therefore,
30
31 288 the analysis using longitudinal disease status information showed that patients with
32
33 289 hypertension had a lower HR than that using baseline status. In contrast, there was small
34
35 290 number of patients (just over 2,000) with CVD only at baseline. Most patients with history
36
37 291 of CVD also had diabetes or hypertension. Around 4,000 healthy participants at baseline
38
39 292 developed CVD during follow-up. We speculated that the increment of the HR from 3.3
40
41 293 (baseline status) to 4.8 (longitudinal data) may be partly attributable to the relative short-
42
43 294 term high risk after a first-ever CVD event. Similarly, we found an increased risk for those
44
45 295 with both hypertension and CVD in the longitudinal analysis compared with that using
46
47 296 baseline status.

48
49 297
50
51 298 Regardless of the existence of other diseases, a history of CVD tended to dominate risk for
52
53 299 mortality, especially over the 5 years of follow-up. Among patients with any cardiometabolic
54
55 300 disease, patients with CVD only had the highest risk, which may reflect a short-term effect
56
57 301 of newly diagnosed CVD. Alternatively, it may also indicate that patients with other
58
59 302 cardiometabolic diseases (e.g., hypertension or diabetes) were likely to be more aware of

1
2
3 303 their health condition. Moreover, among those with cardiometabolic multimorbidity, only
4 304 patients with hypertension and diabetes had significantly lower HR, whereas other groups
5
6 305 (i.e., all with CVD) were broadly similar, even those with all three diseases.
7
8
9 306

10 307 Regarding the HRs for mortality from our study, we compared our findings with other studies.
11
12 308 In ERFC study (involving 91 cohort studies, mainly Western populations)¹⁶, the estimated
13
14 309 HR for mortality was about 2 in participants with one cardiometabolic multimorbidity
15
16 310 condition (type 2 diabetes, coronary heart disease, and stroke) and the association was
17
18 311 multiplicative. However, they did not include hypertension and only used baseline disease
19
20 312 status. We observed a broadly similar HR for patients with diabetes. The higher HR for
21
22 313 patients with CVD (stroke or MI) in our population might be explained by differences in the
23
24 314 overall healthcare services across countries with different economic levels. The estimated
25
26 315 HR for patients with CVD and diabetes (regardless of hypertension) in our study was around
27
28 316 2.5, which was lower than the ERFC estimate (around 3.5–4), but consistent with the
29
30 317 Hispanic Established Population for the Epidemiological study of the Elderly (at 2.4).²² This
31
32 318 may imply that ethnic disparity could explain the differences. We also showed that
33
34 319 cardiometabolic multimorbidity had a more serious impact on those living in urban areas
35
36 320 compared with rural areas. This suggests it is important to consider location differences in
37
38 321 developing strategies to improve public health.
39
40
41 322

42
43 323 The strength of this study was that it was a large-scale, comprehensive study under real-
44
45 324 world circumstances. We used longitudinal data for cardiometabolic disease status to assess
46
47 325 the prevalence and evolution of cardiometabolic multimorbidity during follow-up. However,
48
49 326 this study also had several limitations. First, the CHERRY study is based on a regional
50
51 327 population in a developed area of China, and is not nationally representative. Second, this
52
53 328 study had relatively short follow-up period and the long-term effect of cardiometabolic
54
55 329 multimorbidity needs to be further evaluated. Third, the accurate time of disease onset,
56
57 330 especially hypertension and diabetes, were not available. We could only approximate this
58
59 331 information using the first diagnosis time for these diseases. Information on medication use
60

1
2
3 332 and risk control was also not available. Finally, our laboratory data sources included lipids
4
5 333 measurements for only 25%–30% of the population, which prevented us from model
6
7 334 adjustment for conventional lipids risk factors. However, the ERFC results showed broadly
8
9 335 similar HRs for cardiometabolic multimorbidity and mortality after further adjustment for
10
11 336 smoking, BMI, systolic blood pressure, high-density lipoprotein, total cholesterol,
12
13 337 socioeconomic status, and diet.¹⁶

14 338

16 339 **Conclusions**

18 340 The prevalence of patients with cardiometabolic multimorbidity in a general population in
19
20 341 China more than doubled over 5 years, indicating a rapid evolution of cardiometabolic
21
22 342 multimorbidity. Among all combinations, history of CVD leads the risk for mortality. Our
23
24 343 findings highlight the need for a complementary strategy for primary and secondary
25
26 344 prevention of cardiometabolic diseases in China.

The RECORD statement – checklist of items, extended from the STROBE statement, that should be reported in observational studies using routinely collected health data.

	Item No.	STROBE items	Location in manuscript where items are reported	RECORD items	Location in manuscript where items are reported
Title and abstract					
	1	(a) Indicate the study's design with a commonly used term in the title or the abstract (b) Provide in the abstract an informative and balanced summary of what was done and what was found	1, 2 2	RECORD 1.1: The type of data used should be specified in the title or abstract. When possible, the name of the databases used should be included. RECORD 1.2: If applicable, the geographic region and timeframe within which the study took place should be reported in the title or abstract. RECORD 1.3: If linkage between databases was conducted for the study, this should be clearly stated in the title or abstract.	1, 2 2 2
Introduction					
Background rationale	2	Explain the scientific background and rationale for the investigation being reported	5-6		
Objectives	3	State specific objectives, including any prespecified hypotheses	6		
Methods					
Study Design	4	Present key elements of study design early in the paper	6-7		
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	6-7		

Participants	6	<p>(a) <i>Cohort study</i> - Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up</p> <p><i>Case-control study</i> - Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls</p> <p><i>Cross-sectional study</i> - Give the eligibility criteria, and the sources and methods of selection of participants</p> <p>(b) <i>Cohort study</i> - For matched studies, give matching criteria and number of exposed and unexposed</p> <p><i>Case-control study</i> - For matched studies, give matching criteria and the number of controls per case</p>	6-7	<p>RECORD 6.1: The methods of study population selection (such as codes or algorithms used to identify subjects) should be listed in detail. If this is not possible, an explanation should be provided.</p> <p>RECORD 6.2: Any validation studies of the codes or algorithms used to select the population should be referenced. If validation was conducted for this study and not published elsewhere, detailed methods and results should be provided.</p> <p>RECORD 6.3: If the study involved linkage of databases, consider use of a flow diagram or other graphical display to demonstrate the data linkage process, including the number of individuals with linked data at each stage.</p>	6, 7, eFigure 1 6, 7, eFigure 1 6-7, protocol (BMJ open 2018; 8(2): e019698)
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable.	7-8	RECORD 7.1: A complete list of codes and algorithms used to classify exposures, outcomes, confounders, and effect modifiers should be provided. If these cannot be reported, an explanation should be provided.	7-8
Data sources/ measurement	8	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	6-7, protocol (BMJ open 2018; 8(2): e019698)		

1 2 3 4	Bias	9	Describe any efforts to address potential sources of bias	6-7		
5 6 7 8 9	Study size	10	Explain how the study size was arrived at	6-7, eFigure 1		
10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33 34	Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen, and why	7-8		
35 36 37 38 39 40 41 42 43 44	Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding (b) Describe any methods used to examine subgroups and interactions (c) Explain how missing data were addressed (d) <i>Cohort study</i> - If applicable, explain how loss to follow-up was addressed <i>Case-control study</i> - If applicable, explain how matching of cases and controls was addressed <i>Cross-sectional study</i> - If applicable, describe analytical methods taking account of sampling strategy (e) Describe any sensitivity analyses	8 8 15 7 8		
45 46 47	Data access and cleaning methods		..		RECORD 12.1: Authors should describe the extent to which the investigators had access to the database population used to create the study population.	6-7, eFigure 1

				RECORD 12.2: Authors should provide information on the data cleaning methods used in the study.	6-7, eFigure 1
Linkage		..		RECORD 12.3: State whether the study included person-level, institutional-level, or other data linkage across two or more databases. The methods of linkage and methods of linkage quality evaluation should be provided.	6-7, protocol (BMJ open 2018; 8(2): e019698)
Results					
Participants	13	(a) Report the numbers of individuals at each stage of the study (<i>e.g.</i> , numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed) (b) Give reasons for non-participation at each stage. (c) Consider use of a flow diagram	6-7, 9, eFigure 1 7, eFigure 1 eFigure 1	RECORD 13.1: Describe in detail the selection of the persons included in the study (<i>i.e.</i> , study population selection) including filtering based on data quality, data availability and linkage. The selection of included persons can be described in the text and/or by means of the study flow diagram.	6-7, eFigure 1
Descriptive data	14	(a) Give characteristics of study participants (<i>e.g.</i> , demographic, clinical, social) and information on exposures and potential confounders (b) Indicate the number of participants with missing data for each variable of interest (c) <i>Cohort study</i> - summarise follow-up time (<i>e.g.</i> , average and total amount)	Table 1 9		
Outcome data	15	<i>Cohort study</i> - Report numbers of outcome events or summary measures over time <i>Case-control study</i> - Report numbers in each exposure	11, Figure 3		

		category, or summary measures of exposure <i>Cross-sectional study</i> - Report numbers of outcome events or summary measures			
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (e.g., 95% confidence interval). Make clear which confounders were adjusted for and why they were included (b) Report category boundaries when continuous variables were categorized (c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	Figure 3, eTable 4, 5, 6 9 12		
Other analyses	17	Report other analyses done— e.g., analyses of subgroups and interactions, and sensitivity analyses	eTable 4, 5, 6		
Discussion					
Key results	18	Summarise key results with reference to study objectives	9-12		
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	15	RECORD 19.1: Discuss the implications of using data that were not created or collected to answer the specific research question(s). Include discussion of misclassification bias, unmeasured confounding, missing data, and changing eligibility over time, as they pertain to the study being reported.	15
Interpretation	20	Give a cautious overall interpretation of results considering objectives,	4, 14-16		

		limitations, multiplicity of analyses, results from similar studies, and other relevant evidence			
Generalisability	21	Discuss the generalisability (external validity) of the study results	4, 16		
Other Information					
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	17		
Accessibility of protocol, raw data, and programming code		..		RECORD 22.1: Authors should provide information on how to access any supplemental information such as the study protocol, raw data, or programming code.	4, 6
