NMR Analysis:

In protic solutions such as D₂O, the oxime products reported in this paper would consist of a mixture of not only the ring opened E/Z isomers (major), but also the ring closed β -glycosides (minor) as illustrated in **Figure 1** of the main body of the paper.[2] Given the persistence of these different isomers, it is important to note some of the features present in the ¹H NMR spectra.

First, in the ¹H spectra of **9-15** and **17**, the two downfield signals found between 7.0-8.0 ppm correspond to the open chain E/Z isomers, with the most downfield and dominant signal the E isomer, and the more upfield signal the Z isomer. **Table S1** summarizes the E/Z ratios for the products. What can also be noted from the ¹H NMR spectra of **9-15** and **17** is the presence of several small signals integrating for less than 1H each. These should not be interpreted as impurities, but instead as minor isomer species. All of the products correspond to either a single spot by TLC or a single peak eluted by SEC. Additionally, the products all give rise to the expected number of protons, and finally, they have all been confirmed by high-resolution mass spectrometry (HRMS). For example, from the evaluation of the ¹H NMR of **Compound 9**, it can clearly be seen that the expected ratio of 3:1 for the Boc on the linker (1.40 ppm) to the acetyl protons on the sugar (2.02 ppm) matches that calculated using the peak integrations, despite the sum of the oxime signals at 7.49 ppm (E isomer) and 6.83 ppm (Z isomer) adding to only 0.9 total protons. Based on this information, it is therefore reasonable that the integration of the combined ring opened oxime E and Z signals will not integrate to a full proton, but that some portion of the product is present in the ring-closed form. It would be expected that most of the ring-closed glycosides would predominantly exist in the more favorable β -configuration where the linker is equatorial. A determination of the α/β ratio of these minor products could not be obtained from the current 1D ¹H NMR data given the complexity of the signals overlapping in the region where the anomeric protons would be observed, and the expectation that the α -isomer would only be

present in trace amounts at the most. However, an estimation of the percentage of product in the ring open oxime could be made from the sum of the E and Z integrations (**Table S1**) and was found to range from 71-90%, depending on the sugar.

Table S1: Summary of the E/Z ratios and % ring open oxime for all products. For all but **20** and **21**, this ratio was determined from the ratio of the E and Z proton signals found between 7.0-8.0 ppm in the ¹H spectra. For **20** and **21**, this number was estimated from signals found at 4.15 and 4.28-4.29 ppm, which correspond to the first methylene of the core molecule adjacent to the oxime.[1] ND: Not determined.

Sugar (Compound #)	E/Z Ratio	% Ring open oxime
Monovalent		
GlcNAc (9)	3.5:1	90
Cellobiose (10)	5.5:1	71
Gentiobiose (11)	4.4:1	87
Lactose (12)	7.1:1	81
Maltose (13)	4.4:1	74
Maltotriose (14)	4.6:1	79
Melibiose (15)	5.4:1	83
Trivalent		
Cellobiose (17)	5.4:1	60
Sialic Acid (20)	3.0:1	ND
Disialic Acid (21)	2.7:1	ND

For the ketose-derived products, **20** and **21**, there is no oxime proton present, therefore, no signals appear in the 7.0-8.0 ppm range as was seen for the aldose-derived products, **9-15** and **17**. Instead, a strong signal corresponding to the proximal methylene group of the core adjacent to the oxime was used. This group gives rise to two broad apparent triplet signals at 4.28-29 (E isomer) and 4.15 ppm (Z isomer) for **20** and **21**. These signals were assigned based on their similarity to the linker molecule used in the NMR study reported by Szabo and coworkers.[1] The ratio of these two peaks was therefore used to estimate the E/Z ratio of the ring-opened oxime present. Unfortunately, as there is no E/Z proton available, the percentage of ring-opened oxime could not be estimated for **20** and **21**.
