eMethods

Quality control, GWAS and gene-based analysis

Quality control, imputation and primary association analyses were done using the bioinformatics pipeline Ricopili (available at <https://github.com/Nealelab/ricopili>), developed by the Psychiatric Genomics Consortium (PGC)¹. In order to avoid potential study effects of the 23 genotyping batches within the iPSYCH cohort, each batch was processed separately. Standard procedures for stringent quality control included filters for call rate, Hardy-Weinberg equilibrium, and heterozygosity rates. Each cohort was then phased and imputed using the 1000 Genomes Project phase 3 imputation reference panel² using SHAPEIT³ and IMPUTE2⁴, respectively. Cryptic relatedness and population structure was assessed on high-quality single nucleotide polymorphisms (SNPs) with low linkage disequilibrium (LD) passing filters. Genetic relatedness was estimated in order to identify first and second-degree relatives and one individual was excluded from each related pair. Genetic outliers were identified for exclusion based on principal component analyses using EIGENSOFT⁵ ⁶, contemporarily making use of register-based information on parents' and grandparents' country of origin. The primary analysis in this study is the GWAS, which analyses each SNP for association with phenotype.

GWASs for the 23 genotyping batches in iPSYCH were performed using logistic regression model with the imputed marker dosages (the expected count of one of the alleles) including the first four principal components in order to control for remaining population stratification⁵. Subsequently the results were meta-analysed using an inverse-variance weighted fixed effects model, implemented in METAL (version 2011-03-25)⁷. The international standard for statistical significance is a P-value of 5.0×10^{-8} , which corrects for the approximately one million independent statistical tests conducted. Variants were filtered and included for imputation quality (INFO score) > 0.8 and MAF > 0.01 . After filtering, the meta-analysis included results for 8933939 markers. To explore effects of phenotype definitions on genetic association results, we repeated the analyses separating anxiety disorders and stress-related disorders; and excluding unspecific and other subtypes of these disorders. We then performed 1000 analyses in samples for which we randomly removed the same number of individuals (that had specific subtype) from the case group. The p-value for rs7528604 was assessed as r/n with r being the number of samples with a P-value more or equally significant compared to our analysis removing different subtypes and n being the number of resamples (1000).

Gene-based associations were calculated with MAGMA⁸ using the summary statistics from the main GWAS analyses. Association was tested using the SNP-wise mean model, in which the sum of $-\log_{10}$ (SNP P-value) for SNPs located within the transcribed region was used as test statistic. MAGMA⁸ controls for gene-size, number of SNPs in a gene and LD between markers; LD correction was based on LD estimates from the 1000 Genomes Project phase 3. The gene-based associations were used to analyze sets of genes to test for enrichment of association signals in genes belonging to specific biological pathways or processes (as per MAGMA procedures). We used the MSigDB Canonical Pathways as this list covers a wide variety of gene sets, drawn from different gene-set databases, thus providing results that are not overly dependent on the choice of a narrow set of gene sets. The statistical significance for a gene was defined as a P-value 2.60×10^{-6} ($0.05/19222$ genes tested), for a pathway 2.93×10^{-6} ($0.05/17081$ pathways tested).

Adjusting for mental comorbidity

As the majority of cases in the iPSYCH cohort with anxiety and stress-related disorders by design have another mental disorder (Table 1), we aimed to adjust for mental comorbidity. Models that correct for mental comorbidity therefore supplemented our analyses. In a first model cases with anxiety and stress-related disorders were randomly selected from both iPSYCH cases and controls (N=12665) matching the comorbidity patterns observed in population-based samples (60% mood disorders, 20% ADHD, 5% SCZ, and 5% anorexia⁹⁻¹³, resulting in 10311 cases. This approach follows the idea of a "weighted design" where differences in population size and sampling fraction between the different strata used in the design are considered. A second model included all genotyped individuals of the iPSYCH study (N cases=12096; N controls=42215) and design phenotypes were employed as covariates (schizophrenia, ADHD, anorexia

nervosa, and affective disorders)¹⁴. In our most stringent sensitivity analyses we further employed a propensity-score-matched design, matching cases and controls on mental comorbidity status, principal components, genotyping batches, and age using the R 3.1.0 package ‘MatchIt’ (using the ‘nearest neighbor’ algorithm). After matching a total of 11599 individuals with a comorbid anxiety or stress-related disorder and 11599 without comorbid disorders remained for analysis using a Cochran-Mantel-Haenszel test. Inherent to the design this analysis was least powered to find genetic variants for anxiety and stress-related disorders across all genome-wide designs used in our study. All these sensitivity analyses resulted in a reduction of the number of cases, albeit with varying impact on power. We also performed a second set of sensitivity analyses targeted at identifying a significant impact of comorbid depression or schizophrenia cases on our association results for *PDE4B*. For these analyses, we first performed a standard association test for rs7528604 (see above) but removing individuals with comorbid depression or schizophrenia from the case group (see eFigure 10). We then performed 1000 analyses in samples for which we randomly removed the same number of individuals (that had comorbid depression or schizophrenia) from the case group. The p-value for rs7528604 was assessed as r/n with r being the number of samples with a P-value more or equally significant compared to our analysis removing the comorbid depression or schizophrenia cases and n being the number of resamples (1000). Finally, analyses were supplemented by including obsessive-compulsive disorders (OCD) among the anxiety and stress-related disorders.

SNP heritability and genetic correlation with other traits

LD score regression was used to dissect the relative contribution of polygenic effects and confounding factors, such as cryptic relatedness, sample overlap and population stratification, to deviation from the null in the genome-wide distribution of GWAS χ^2 statistics. Analysis was performed using pre-computed LD scores based on 378 European-ancestry individuals from the 1000 Genomes Project phase 3 (available on <https://github.com/bulik/ldsc>) and summary statistics for the European-ancestry GWAS to ensure matching of population LD structure. The influence of confounding factors was tested by comparing the estimated intercept of the LD score regression to the expected value under the null hypothesis of no confounding from e.g. population stratification. We also calculated the heritability on the liability scale in our main GWASs. Prevalence was specified as 20% for the combination of anxiety and stress-related disorders^{15, 16}, 12% for anxiety disorders alone and 15% for stress-related disorder alone. Using LD score regression SNP heritability was partitioned by functional category and tissue association^{17, 18}. Partitioning was performed for 53 overlapping functional categories, as well as 220 cell-type-specific annotations grouped into 10 cell-type categories¹⁹. Enrichment in the heritability of a functional category was defined as the proportion of SNP heritability explained divided by the proportion of SNPs¹⁹. Test for enrichment in the heritability of SNPs located in cell-type-specific regulatory elements was evaluated in two ways. One by using the 220 cell-type-specific annotations that have been grouped into 10 cell-type groups as previously described¹⁹. These annotations are based on cell-specific histone markers, related to H3K4me1²⁰, H3K4me3²⁰, H3K9ac²⁰ and H3K27ac²¹. In these analyses, we tested if the cell-group specific annotations contributed significantly to the SNP heritability when controlling for the annotations in the full baseline model. Further, we expanded the cell-type specific heritability analysis by including an annotation based on information about H3K4Me1 imputed gapped peaks excluding the broad MHC-region (chr6: 25-35MB), generated by the Roadmap Epigenomics Mapping Consortium^{21, 22}. This mark has previously been used with success in identifying significant enrichments in tissues/cells and often in a biologically plausible manner²¹.

Genetic correlations (r_g) correlations were tested for 228 phenotypes with publicly available GWAS summary statistics using LD Hub²³. For these analyses, statistical significance was set using the Bonferroni correction, which is conservative given non-independence of the traits. A P-value of 2.19×10^{-4} (0.05/228 traits tested) was considered significant. For a given pair of traits, LD score regression estimates the expected population correlation between the best possible linear SNP-based predictor for each trait, restricting to common SNPs. Such correlation of genetic risk may reflect a combination of co-localization, pleiotropy, shared biological mechanisms, and causal relationships between traits. Please see eTables 4 (naïve design), 6 (prevalence design), 8 (covariates design), 10 (propensity design). for a full list of results.

Genetic correlations (rG) were also tested for 596 traits from the UK Biobank study (UKBB), made publicly available at <https://sites.google.com/broadinstitute.org/ukbbgwasresults>. Details on how the GWASs in UKBB have been conducted are available here: <http://www.nealelab.is/blog/2017/9/11/details-and-considerations-of-the-uk-biobank-gwas>. We restricted our analyses to those traits that showed z-scores > 2 in their heritability analyses. We would like to note that (as mentioned on the blog referenced above) the

UKBB GWAS results are still preliminary in their nature and we therefore would like to advise readers to take the results of our analyses with a grain of salt. Nonetheless, we still believe that they allow for some interesting insights and together with the results from LD Hub and our other analyses can shed more light on the impact of comorbid traits and phenotypes on anxiety and stress related disorders. A P-value of 8.39×10^{-5} (0.05/596 traits tested) was considered significant. For all traits that show a significant correlation after Bonferroni correction for multiple testing results can be found in eTables 5 (naïve design), 7 (prevalence design), 9 (covariates design), 11 (propensity design).

Polygenic risk score

Polygenic risk score (PRS)²⁴ were constructed in our sample in order to explore polygenic heterogeneity across diagnostic subtypes and comorbidities. PRS were calculated by multiplying the natural log of the odds ratio of each variant by the allele-dosage (imputation probability) and whole-genome PRS were obtained by summing values over variants for each individual²⁴. After scoring, PRS were normalized and used as continuous markers. We regressed the normalized scores on anxiety and stress-related subgroups while including covariates for batches and principal components in a multivariate regression²⁵. We focused on unique phenotypes showing strong genetic correlation ($P < 5.0 \times 10^{-7}$) with anxiety and stress-related disorders in our LD Hub analyses (schizophrenia¹, depression²⁶, subjective well-being²⁷, and neuroticism²⁷), excluding the iPSYCH samples from the schizophrenia and depression dataset.

Mouse model of chronic psychosocial stress

To establish the effect of chronic psychosocial stress on the brain gene expression levels of Pde4b, we employed the chronic social defeat stress (CSDS) model²⁸. We obtained 5-week old male mice from two inbred strains: C57/BL6NCrl (B6, innately non-anxious strain) and DBA/2NCrl (D2, innately anxious strain; Charles River, Sulzfeld, Germany) and let them acclimatize for one week. Mice were exposed to a resident aggressor mouse (Clr-CD1 strain) for max. 10 min followed by housing in adjacent compartments for 24 h, repeated once per day for 10 days with a novel resident aggressor. Control mice were housed adjacent to another mouse, switching cage-mates daily but without physical exposure²⁸.

Twenty-four hours after the last CSDS session we tested all mice for social aversion using two trials. For the first trial the mice were placed for 150 s into an arena containing a perforated Plexiglass cylinder. For the second trial the empty cylinder was replaced by one containing a novel Clr-CD1 mouse. The ratio of time the mouse spent in the area around the cylinder in the trial containing the mouse compared to the trial without a social target was used to determine whether each defeated mouse was resilient or susceptible to CSDS. We defined a susceptible mouse as one which showed a marked reduction in this ratio compared to the same-strain control mice collected from several cohorts (1 standard deviation below the control mean). The remaining mice with scores above this threshold were classified as resilient as their behavior remained similar to the same-strain controls. After this test the mice were housed in single-cages.

One week after the end of CSDS we dissected the medial prefrontal cortex (mPFC) and ventral hippocampus (vHPC) for RNA sequencing (RNA-Seq). All animal procedures were approved by the Regional State Administration Agency for Southern Finland (license numbers ESAVI-3801-041003-2011 and ESAVI/2766/04.10.07/2014) and carried according to directive 2010/63/EU of the European Parliament and of the Council, and the Finnish Act on the Protection of Animals Used for Science or Educational Purposes (497/2013). For more details on these experiments see Laine et al.²⁹.

Gene expression profiling

Total RNA was extracted using TriReagent. For RNA-seq we carried out rRNA depletion using Ribo-Zero (Illumina, San Diego, CA, USA) followed by fragmentation with an S2 ultrasonicator (Covaris Inc., Woburn, MA, USA). mRNA sequencing libraries were prepared with Nextera (Illumina, vHPC samples) or ScriptSeq v2 (Epicentre, Madison, WI, USA, mPFC samples) kits. The vHPC samples were sequenced by the Finnish Institute of Molecular Medicine (FIMM) and the mPFC samples by the Institute of Biotechnology at the University of Helsinki, using Illumina High-Seq 2000 and NextSeq 500, respectively. Following quality control, we aligned the mRNA reads with STAR 2.5.0c³⁰ to the mouse genome GRCm38. Data normalization and differential expression analysis were carried out with ComBat³¹ and limma v3.32.5³².

Whole transcriptome level multiple testing correction was done with the Benjamini-Hochberg method³³, after which the expression levels of *Pde4b* was extracted from the dataset.

eTable 4. Genetic correlations for “naïve” Design

All results from LDhub analyses. Trait= trait against which genetic correlation was calculated. PMID= PMID for publication that belongs to tested summary statistics. rG= genetic correlation. SE= standard error for genetic correlation. Z= Z-score. p= P-value for genetic correlation analysis. ethnicity= sample ethnicity for sample referenced in “Trait” column. h2_obs= Heritability on the observed scale for sample referenced in “Trait”. se= standard errors for variable reported in the cell to the left (i.e. h2_obs, ht_int, gcov_int). h2_int= LD score intercept for sample referenced in “Trait”. gcov_int= cross-trait LD Score regression intercept.

eTable 5. Genetic correlations for “naïve” Design (UKBB traits)

All results from LDhub analyses. Trait= trait against which genetic correlation was calculated. ethnicity= sample ethnicity for sample referenced in “Trait” column. rG= genetic correlation. SE= standard error for genetic correlation. z= Z-score. p= P-value for genetic correlation analysis. h2_obs= Heritability on the observed scale for sample referenced in “Trait”. se= standard errors for variable reported in the cell to the left (i.e. h2_obs, ht_int, gcov_int). h2_int= LD score intercept for sample referenced in “Trait”. gcov_int= cross-trait LD Score regression intercept.

eTable 6. Genetic correlations for “prevalence” Design

All results from LDhub analyses. Trait= trait against which genetic correlation was calculated. PMID= PMID for publication that belongs to tested summary statistics. rG= genetic correlation. SE= standard error for genetic correlation. Z= Z-score. p= P-value for genetic correlation analysis. ethnicity= sample ethnicity for sample referenced in “Trait” column. h2_obs= Heritability on the observed scale for sample referenced in “Trait”. se= standard errors for variable reported in the cell to the left (i.e. h2_obs, ht_int, gcov_int). h2_int= LD score intercept for sample referenced in “Trait”. gcov_int= cross-trait LD Score regression intercept.

eTable 7. Genetic correlations for “prevalence” Design (UKBB traits)

All results from LDhub analyses. Trait= trait against which genetic correlation was calculated. ethnicity= sample ethnicity for sample referenced in “Trait” column. rg= genetic correlation. SE= standard error for genetic correlation. z= Z-score. p= P-value for genetic correlation analysis. h2_obs= Heritability on the observed scale for sample referenced in “Trait”. se= standard errors for variable reported in the cell to the left (i.e. h2_obs, ht_int, gcov_int). h2_int= LD score intercept for sample referenced in “Trait”. gcov_int= cross-trait LD Score regression intercept.

eTable 8. Genetic correlations for “covariate” Design

All results from LDhub analyses. Trait= trait against which genetic correlation was calculated. PMID= PMID for publication that belongs to tested summary statistics. rG= genetic correlation. SE= standard error for genetic correlation. Z= Z-score. p= P-value for genetic correlation analysis. ethnicity= sample ethnicity for sample referenced in “Trait” column. h2_obs= Heritability on the observed scale for sample referenced in “Trait”. se= standard errors for variable reported in the cell to the left (i.e. h2_obs, ht_int, gcov_int). h2_int= LD score intercept for sample referenced in “Trait”. gcov_int= cross-trait LD Score regression intercept.

eTable 9. Genetic correlations for “covariate” Design (UKBB traits)

All results from LDhub analyses. Trait= trait against which genetic correlation was calculated. ethnicity= sample ethnicity for sample referenced in “Trait” column. rG= genetic correlation. SE= standard error for genetic correlation. z= Z-score. p= P-value for genetic correlation analysis. h2_obs= Heritability on the observed scale for sample referenced in “Trait”. se= standard errors for variable reported in the cell to the left (i.e. h2_obs, ht_int, gcov_int). h2_int= LD score intercept for sample referenced in “Trait”. gcov_int= cross-trait LD Score regression intercept.

eTable 10. Genetic correlations for “propensity” Design

All results from LDhub analyses. Trait= trait against which genetic correlation was calculated. PMID= PMID for publication that belongs to tested summary statistics. rG= genetic correlation. SE= standard error for genetic correlation. Z= Z-score. p= P-value for genetic correlation analysis. ethnicity= sample ethnicity for sample referenced in “Trait” column. h2_obs= Heritability on the observed scale for sample referenced in “Trait”. se= standard errors for variable reported in the cell to the left (i.e. h2_obs, ht_int, gcov_int). h2_int= LD score intercept for sample referenced in “Trait”. gcov_int= cross-trait LD Score regression intercept.

eTable 11. Genetic correlations for “propensity” Design (UKBB traits)

All results from LDhub analyses. Trait= trait against which genetic correlation was calculated. ethnicity= sample ethnicity for sample referenced in “Trait” column. rG= genetic correlation. SE= standard error for genetic correlation. z= Z-score. p= P-value for genetic correlation analysis. h2_obs= Heritability on the observed scale for sample referenced in “Trait”. se= standard errors for variable reported in the cell to the left (i.e. h2_obs, ht_int, gcov_int). h2_int= LD score intercept for sample referenced in “Trait”. gcov_int= cross-trait LD Score regression intercept.

eTable 12. SNP Heritability estimates across varying analytical designs

All heritabilities are calculated using LDscore regression. h2_liab= Heritability at the liability scale. SE= standard error for SNP heritability. k= prevalence used in the analysis.

Design	h2_liab	SE	k
"Naïve"	0.2816	0.0267	0.2
Prevalence	0.2617	0.0278	0.2
Covariates	0.0813	0.0184	0.2
Covariates	0.0908	0.0205	0.3
Covariates	0.0960	0.0217	0.4
Covariates	0.0977	0.0221	0.5
Propensity	0.1316	0.0341	0.2
Propensity	0.1470	0.0381	0.3
Propensity	0.1555	0.0403	0.4
Propensity	0.1583	0.0410	0.5
