This supplementary material has been provided by the authors to give readers additional information about their work.

eMethods. Detailed Methods

We limited our analysis to ages 16-84 years, for which both wage and employment data and state population estimates for age-standardization were available in single years. Eleven decedents with unknown age (0.002%) were excluded from this analysis. Data on annual median earnings of employed primary or sole salary and wage workers in 2015 were stratified by age group (16-19, 20-24 ... 80-84 years), sex, education level, and employment status (non-worker, including those not in the labor force and unemployed persons; employed part-time; employed full-time).

We show results for all ages combined; results by age group for adolescents and young adults aged 16-39 years and adults in five other age groups (40-49, 50-59, 60-69, 70-79, and 80-84 years) are shown only for all cancers combined at the national level due to relatively modest numbers of cancer deaths for many cancer sites or by state, particularly in younger age groups. The 2016 Current Population Survey March supplement was used to obtain earnings data due to the survey's inclusion of an annual earnings estimate for respondents. Annual earnings data were based on the reported 2015 earnings of employed primary or sole wage and salary workers, excluding all self-employed persons regardless of incorporation status, before taxes and other deductions and included any overtime pay, commissions, or tips usually received, consistent with definitions used in U.S. Bureau of Labor Statistics' earnings reports for the United States. As some older individuals aged ≤ 84 years were expected to live a few years beyond age 84 years in the absence of premature death, we used annual earnings data of ages 80-84 years to estimate lost earnings during the residual life expectancy beyond age 84 years. To quantify the effects of uncertainty in wage and employment status data and generate confidence intervals for our estimates, we applied a simulation method (using standard errors from the data source, i.e., the 2016 Current Population Survey March supplement) with 1000 replications for each age group and sex stratum. Average annual earnings for each age and sex group was calculated using the following equation, in which P represented proportions of full- or part-time employees and E represented median annual earnings in the corresponding group:

$$\text{Average annual earnings} = (P_{\text{full-time}} \times E_{\text{full-time}}) + (P_{\text{part-time}} \times E_{\text{part-time}})$$

The reported total lost earnings, lost earning rates, and average lost earnings per death are the medians of the corresponding values from 1000 replications, and the limits of 95% confidence intervals are 25th and 975th ordered values. Because lost earnings overall and by sex were from separate simulation models and due to rounding, lost earnings in men and women may not add up to totals.

Additional analysis by education level. We estimated lost earnings based on decedents' education level in an additional analysis because deaths from many cancer sites occur more commonly in persons with lower education (and often, lower earnings) than higher education due to higher exposure to known cancer risk factors (e.g., smoking) or more limited access to care; thus, lost earnings estimated based on median earnings for all education levels combined may overestimate the actual amount of lost earnings. However, results based on decedents' education level might be more difficult to interpret when comparing lost earning rates across states, because in this case a lower rate in a state might not necessarily or entirely reflect lower cancer burden, as it could also be a result of greater proportions of people with lower education levels and earnings in that state. For example, between two states with the same PYLL rate, the state with lower education level would have a lower age-standardized lost earnings rate. Therefore, although we presented results from both approaches, we highlighted the estimates based on median earnings for all education levels combined to focus more on differences in the burden of cancer rather than variations in education levels across states.

Due to state-level differences in how educational attainment is reported on death certificates, highest attained education level was collapsed into three broad groups (high school diploma/GED or less, some college or baccalaureate degree, or more than baccalaureate) to ensure consistency across states with different reporting standards. The attained education level for cancer deaths with missing information ($N = 19,663$; 4.0% of all cancer deaths included in this study) was imputed based on the distribution of education levels in the corresponding age (single year) and sex.

Average annual earnings for each age, sex, and education group using the equation described above. Age-, sex-, and education-specific lost earnings were calculated by multiplying person-years of life lost (PYLL) by the annual median earning in the corresponding group in 2015 U.S. dollars. To quantify the effects of uncertainty in wage and employment status data and generate confidence intervals for our estimates, we applied a simulation method with 1000 replications for each age group, sex, and education level stratum. As those who died before age 30 years might have attained a higher education level had they not died prematurely, we adjusted their future annual lost earnings based on education levels in corresponding age groups until age 30 years, and for older ages (≥ 30 years until the end of residual life expectancy), based on education levels in ages 30-34 years. For example, for cancer deaths occurred at age 16-19 years, education levels at ages 20-24, 25-29, and 30-34 years were used for adjustment of future lost earnings in ages 20-24, 25-29, and ≥ 30 years, respectively. PYLL and lost earnings were summed over all age and education groups to obtain total PYLL and lost earnings for each cancer site by sex. All other statistical analyses to calculate PYLL and lost earnings (including discounting) were similar to those described in the Methods in the article's text.

Because earnings vary by educational attainment and death certificates are state-level, this sensitivity analysis incorporates differing economic conditions across states.

Earn., earnings.

Percentages of non-workers are not shown. Data are from the U.S. Census Bureau's 2016 Current Population Survey March supplement (for more information, see eMethods).

* A negligible proportion of those aged 16-19 years reported having a "More than baccalaureate" degree. As none of cancer deaths in ages 16-19 years in this study had a "More than baccalaureate" degree, here we do not report employment data for that group.

Age-std., age-standardized; PYLL. Person-years of life lost.

Age-standardized PYLL and lost earning rates are age-adjusted to the 2000 U.S. Standard Population. Individual cancer sites at the national level are ordered by total lost earnings. States are ordered alphabetically. In the 'National-level results' section, rates by age group for all cancers combined are age-specific rates. Other rates are for the entire U.S. population, including ages <16 and >84 years. Head and neck cancers include cancers of the lip, oral cavity, pharynx, nose, nasal cavity, middle ear, and larynx. In the 'State-level results' section, the number of deaths, total PYLL, and total lost earnings for the United States were calculated by summing up corresponding numbers for all 50 states and the District of Columbia; using these numbers, average lost earnings per death and age-standardized PYLL and lost earning rates for the United States were calculated. Because lost earnings overall and by sex were from separate simulation models and due to rounding, lost earnings in men and women may not add up to totals.

^ Statistic not displayed due to fewer than 16 deaths.

eTable 4. Lost Earnings (Calculated Based on Decedents' Education Level) for Major Cancer Sites in Ages 16-84 Years by Sex at the National- and State-Level, 2015

Age-std., age-standardized.

Age-standardized lost earning rates are age-adjusted to the 2000 U.S. Standard Population. States are ordered alphabetically. In the 'National-level results' section, crude rates by age group for all cancers combined are age-specific rates. Other crude rates are for the entire U.S. population, including ages <16 and >84 years. Head and neck cancers include cancers of the lip, oral cavity, pharynx, nose, nasal cavity, middle ear, and larynx. In the 'State-level results' section, total lost earnings for the United States were calculated by summing up corresponding numbers for all 50 states and the District of Columbia; using these numbers, age-standardized lost earning rates and average lost earnings per death for the United States were calculated. Average lost earnings per death by age group were calculated by dividing total PYLL and lost earnings, respectively, by the number of cancer deaths in each sex and age group. Because lost earnings overall and by sex were from separate simulation models and due to rounding, lost earnings in men and women may not add up to totals.

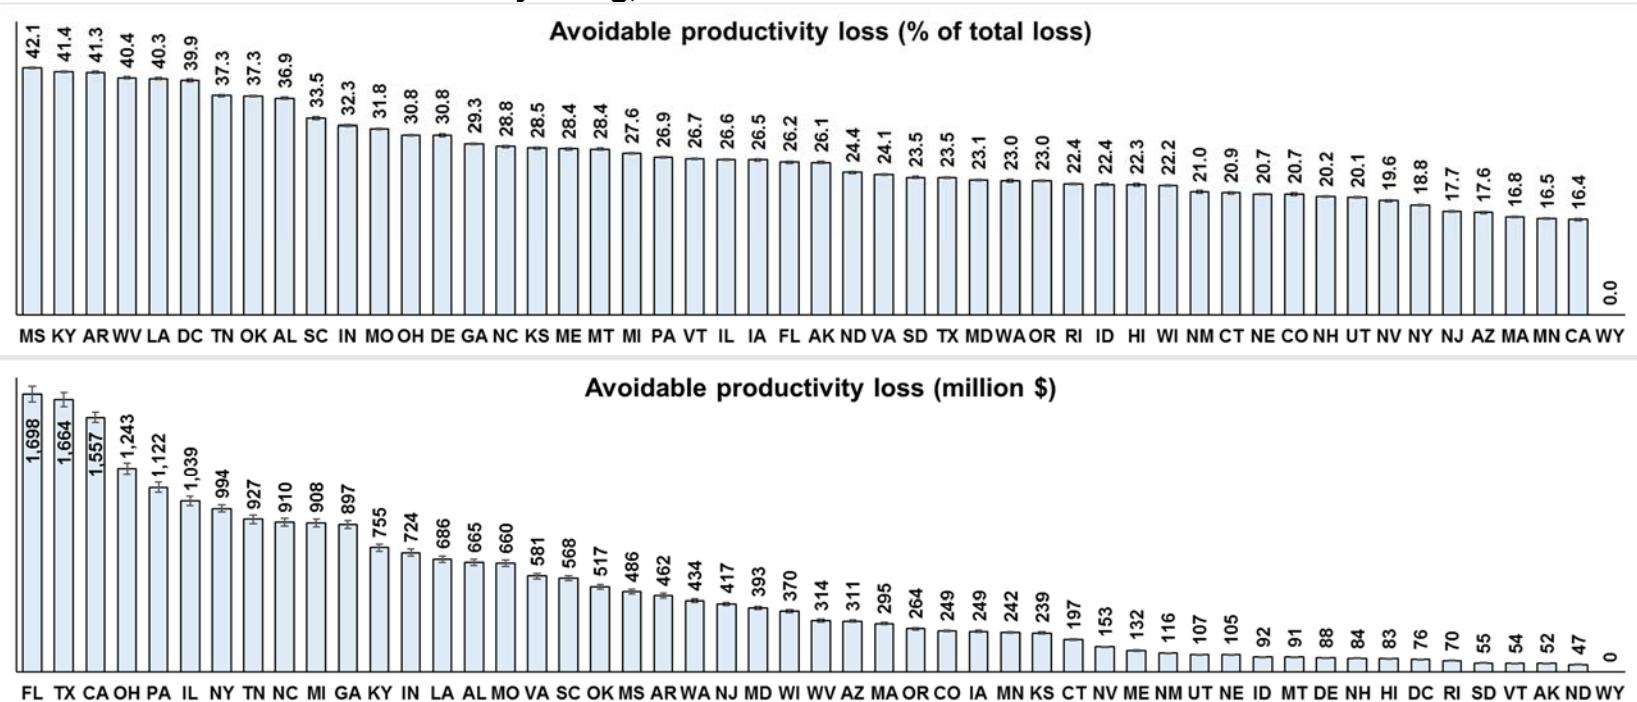

[^] Statistic not displayed due to fewer than 16 deaths.

eFigure 1. Potentially Avoidable PYLL and Lost Earnings in Ages 16-84 Years in Both Sexes Combined by State if Age-Specific PYLL or Lost Earning Rates for All Cancers Combined in All States Were Similar to Those in Utah, 2015

The overall potentially avoidable PYLL and lost earnings in the United States in this scenario was 2,383,447 person-years and \$27.7 billion (95% confidence interval, \$26.9 billion – \$28.5 billion; 29.3% of total lost earnings), respectively. The bars in diagrams for lost earnings represent 95% confidence intervals.

eFigure 2. Potentially Avoidable Lost Earnings (Calculated Based on Decedents' Education Level) in Ages 16-84 Years in Both Sexes Combined by State if Age-Specific Lost Earning Rates for All Cancers Combined in All States Were Similar to Those in Wyoming, 2015

The overall potentially avoidable lost earnings in the United States in this scenario was \$22.9 billion (95% confidence interval, \$22.3 billion – \$23.5 billion; 24.3% of total lost earnings), respectively. The bars in the figure represent 95% confidence intervals.
