Data S1 (Microsoft Excel format). Relative concentration of PVY RNA as measured in the leaves of *N. clevelandii* including tables S3 to S5:

Table S3. Relative concentration of PVY RNA as measured in bombarded leaves of *N. clevelandii* 7 dpb (experiment 1).

Table S4. Relative concentration of PVY RNA as measured in upper nonbombarded leaves of *N. clevelandii* 14 dpb (experiment 1).

Table S5. Relative concentration of PVY RNA as measured in bombarded leaves of *N. clevelandii* (experiment 2).

Supplementary Text S1. Detailed description of protein-protein interactions in PVY

Numerous protein-protein interactions in the cluster of 13 interconnected CP units are translationally repeated along the axis of the viral filament (Fig. 2A and fig. S5). The CPⁿ N-terminal region stretches all the way to CPⁿ⁻¹⁰ unit. The groove between the β -hairpin loop and helices α 3 and α 2 in CPⁿ⁻¹⁰ core nests CPⁿ residues Val44 – Lys48 in a combination of electrostatic and hydrophobic interactions, and the same is true for the CPⁿ⁺¹⁰ – CPⁿ interface (fig. S5A). Interactions between CPⁿ – CPⁿ⁻² (counterpart CPⁿ⁺² – CPⁿ) are limited to the salt bridge between Lys58 at the sharp turn in the N-terminal region of CPⁿ, and Asp138 in the loop of CPⁿ⁻² β -hairpin (fig. S5B). CPⁿ – CPⁿ⁻¹ interactions (counterpart CPⁿ⁺¹ – CPⁿ) are mainly based on CPⁿ residues Ala49 – Asn82 folding on the outer surface of the CPⁿ⁻¹ core (fig. S5C), with alternating electrostatic and hydrophobic interactions anchoring the N-terminal peptide of CPⁿ to the core of CPⁿ⁻¹. The CPⁿ core sits on top of the CPⁿ⁻⁸ and CPⁿ⁻⁹ cores (fig. S5D). These interactions are mainly electrostatic and are mirrored by interactions between CPⁿ, CPⁿ⁺⁸ and CPⁿ⁺⁹ units. The C-terminal region of CPⁿ unit is completely defined and extends inside the lumen all the way up to the core of CPⁿ⁺¹⁷ (Fig. 2A). The CPⁿ α 8-helix (Val211 – Leu225) and the first residues of the extended C-terminal region, Lys226 – Arg231, are stacked between C-terminal regions of CPⁿ⁻⁸ and CPⁿ⁻⁹, based on mixed electrostatic and hydrophobic interactions (fig. S5E). The following CPⁿ residues, Leu232 – Ile239, are sandwiched between α 8-helices of CPⁿ⁺⁸ and CPⁿ⁺⁹, the core residues Val187 – Arg191 of CPⁿ⁺⁸, and Asn245 – Thr251 of CPⁿ⁻⁹ (fig. S5F). CPⁿ residues Ser240 – Thr251 run along Ser227 – Ile239 of CPⁿ⁺⁹, while Ser227 – Ile239 in the neighboring CPⁿ⁺⁸ deviate away from CPⁿ to run along Thr240 – Thr251 of CPⁿ⁻¹ (fig. S5G). C-terminal residues Glu244 – Glu252 of CPⁿ run in parallel along the α 8-helix of CPⁿ⁺¹⁷, predominantly based on electrostatic interactions (fig. S5H). Due to helical symmetry, the α 8-helix of CPⁿ interacts in the same manner with C-terminal residues of CPⁿ⁻¹⁷. The interactions of approximately 20 final residues (Glu247 – Met267) further strengthen the contacts between CPⁿ and CPⁿ⁻¹ (fig. S5I). After Thr251, the extended C-terminal peptide of CPⁿ undergoes two sharp turns, which end in Thr260, from which it extends to the final residue Met267 again, but this time in almost perpendicular direction to the filament. This final region (Thr260 – Met267) is sandwiched between similar regions of CPⁿ⁻¹ and CPⁿ⁺¹ (fig. S5I).

Supplementary Text S2. Detailed description of protein-protein interactions in VLP

The interaction network in VLPs is decreased to only five CPs (Fig. 3D), not taking into account potential random interactions between the flexible C-terminal regions. Each ring is held together via interactions between neighboring core domains. Similar to authentic virions, the N-terminal region between residues Met54 and Ala85 of CPⁿ acts as a clip and fixes CPⁿ onto the core of CPⁿ⁻¹ (Figs. 3, C to E). Electrostatic interactions prevail (fig. S8), with a patch of hydrophobic interactions between α 1-helix of CPⁿ and α 5 of CPⁿ⁻¹ core (Fig. 3E, fig. S8B). The inter-ring connection is limited to interactions between the extended region of residues Thr43 to Ala49 of CPⁿ and those of the α -hairpin loop and helices α 2 - α 4 of CPⁱ⁻² (Fig. 3E). In contrast to virions (Fig. 1D), there is no interaction between the N-terminal region of CPⁿ and CPⁿ⁻² in VLP.

Supplementary Text S3. Importance of the CP N terminus for longitudinal assembly of VLPs

To study the importance of the N-terminal region in longitudinal assembly of octameric VLP rings, N-terminal deletion mutants were prepared (Fig. 5, A and B). Of these, only the mutant proteins Δ N49 and Δ N69 were soluble (Fig. 5B) and both had circular dichroism spectra comparable to wild-type CP (fig. S3E). SEC-MALS analysis of purified Δ N49 protein revealed a 210 kDa complex, consistent with the octameric assembly of Δ N49 (fig. S3D). In addition, a smaller population of high molecular weight aggregates were also present, which were not filamentous structures, as confirmed by negative stain TEM (Fig. 5B, middle panel). Based on the VLP interaction network, Δ N49 should form octameric rings and Δ N69 should remain monomeric (Fig. 3E). Indeed, cryo-EM revealed that Δ N49 oligomers were octameric rings with the tendency to adhere to each other, thereby forming stacks of up to four rings (Fig. 5B, bottom panel). No filaments were detected for Δ N69 (Fig. 5B, middle panel) and SEC-MALS detected monomers and unspecific aggregates (fig. S3D).

Supplementary Text S4. Redundancy of CP C termini for VLP filament or octameric ring

CP C-terminal deletion mutant proteins were prepared to assay the impact of the disordered C-terminus on VLP filament shape and stability (Fig. 5, A and C). These mutant proteins were all soluble, and similarly to PVY virions and VLPs formed from wild-type CP, partial proteolysis could be observed in final purified samples (Fig. 5C, upper panel right, fig. S3C). Interestingly, filament formation was preserved even in the absence of the 60 C-terminal residues, e.g. up to Ser207, which is located at the start of the final α 8-helix (Fig. 5C, middle and bottom panels). We further purified and characterized Δ C40, which still includes the α 8 helix, and Δ C60, which lacks it. Circular dichroism spectra (fig. S3E) and negative stain TEM images of purified VLPs formed of Δ C40 and Δ C60 (Fig. 5C, middle and bottom panel right) were comparable to wild-type VLPs (fig. S7A). In the case of Δ C40 VLPs we could observe the inner channel of the filament (Fig. 5C, middle panel right, inset).

We prepared a double deletion mutant, Δ N49C40 (Fig. 5, A and D), to remove the flexible C-terminal extension still present in the octameric ring of Δ N49. Interestingly, in addition to octameric rings detected by SEC-MALS (fig. S3D), loosely bound filaments (generally less than 500 nm long) were detected by negative stain TEM (Fig. 5D, upper and middle panel left), which were significantly longer than Δ N49-derived stacks of rings (Fig. 5B bottom). This showed that the C-terminal region is not only dispensable for VLP filament formation, but may even contribute to its destabilization. Indeed, after we removed the C-termini of deletion mutants Δ N29 and Δ N39 (which were insoluble), the resulting Δ N29C40 and Δ N39C60 proteins could form long filaments (Fig. 5D).

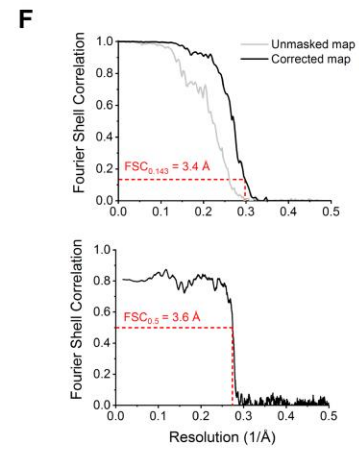

Fig. S1. Cryo-EM data collection, image processing, and model building for the PVY virion. (A) Negative-stain TEM micrograph of PVY. Inset: an example of a damaged PVY filament. (B) Cryo-EM micrograph of PVY. (C) Examples of PVY 2D class averages. (D) Sum of the power spectra obtained for 53 selected PVY segments. The black lines highlight the $n = -1$ layer line at $1/35 \text{ \AA}$, the $n = 8$ layer line at $1/43 \text{ \AA}$, and $n = -9$ layer line at $1/160 \text{ \AA}$ corresponding to one-start left-handed helix. (E) Flowchart of the data collection and processing for the PVY virion. (F) Fourier shell correlation (FSC) curves for the final reconstruction of PVY density map (top) and between the PVY model and density map (bottom). (G) Local resolution analysis of one turn of the PVY filament (top) and one extracted CP unit (below), estimated using MonoRes (34). (H) Surface representation of density map with a structural model of PVY CP (N-terminal region: red, core: gray, C-terminal region: blue). (I) The densities of two PVY CP segments are shown in a mesh representation (maps contoured at 3σ) with the corresponding atomic model within, showing the resolution of individual side chains.

Fig. S2. Consensus sequence alignment of potyviral CPs. CP sequences of PVY (36), banana bract mosaic virus (BBrMV) (64), Bidens mottle virus (BiMoV) (9), Bidens mosaic virus (BiMV) (4), Brugmansia mosaic virus (BruMV) (5), bean yellow mosaic virus (BYMV) (45), chilli veinal mottle virus (ChiVMV) (15), clover yellow vein virus (CIYVV) (13), johnsongrass mosaic virus (JGMV) (28), lettuce mosaic virus (LMV) (12), peanut mottle virus (PeMoV) (12), pepper mottle virus (PepMoV) (7), pepper yellow mosaic virus (PepYMV) (10), pepper severe mosaic virus (PeSMV) (5), papaya ringspot virus (PRSV) (44), Peru tomato mosaic virus (PTV) (6), potato virus V (PVV) (32), soybean mosaic virus (SMV) (59), sunflower chlorotic mottle virus (SuCMoV) (5), tobacco etch virus (TEV) (77), turnip mosaic virus (TuMV) (73) and watermelon mosaic virus (WMV) (54) were obtained from NCBI database (<https://www.ncbi.nlm.nih.gov/>) (number of sequences for each CP is in brackets) and aligned with ClustalW algorithm in MEGA7 (56). Consensus sequences were created in BioEdit (57) and aligned using identity protein weight matrix in MEGA7. ‘X’: non-consensus positions at frequency threshold of 60 %. The alignment is presented using ESPript 3.0 (<http://espript.ibcp.fr/ESPript/ESPript/>). Green box: the conserved DAG site; green arrows: conserved RNA binding residues. Above: a scheme of PVY CP secondary structure.

Fig. S3. Biophysical characterization of PVY virions and various VLP constructs. (A) SDS-PAGE bands transferred to a PVDF membrane reveal proteolysis of the CP in both the PVY and VLP samples. (B) Edman sequencing of bands in (A). The intact CP unit is found in band 'a' of both, PVY and VLP, while additional lower bands 'b-d' represent proteolysed CP units. Sequence reads of each band are displayed together with their assigned number of missing N-terminal amino acids. (C) Comparison of MALDI-TOF mass spectra of PVY and different VLP constructs. The peaks corresponding to full-length proteins are marked with *. Peaks at smaller m/z representing truncated protein species are observed in all the spectra except for $\Delta N49$ and $\Delta N49C40$. (D) SEC-MALS chromatograms (solid lines: UV response, dashed lines: light scattering response at 90° angle) for wild-type VLP filaments and non-filamentous constructs $\Delta N69$, $\Delta N49$ and $\Delta N49C40$. (E) Circular dichroism spectra of wild-type VLP and deletion mutants $\Delta N49$, $\Delta N69$, $\Delta C40$, $\Delta C60$ and $\Delta N49C40$.

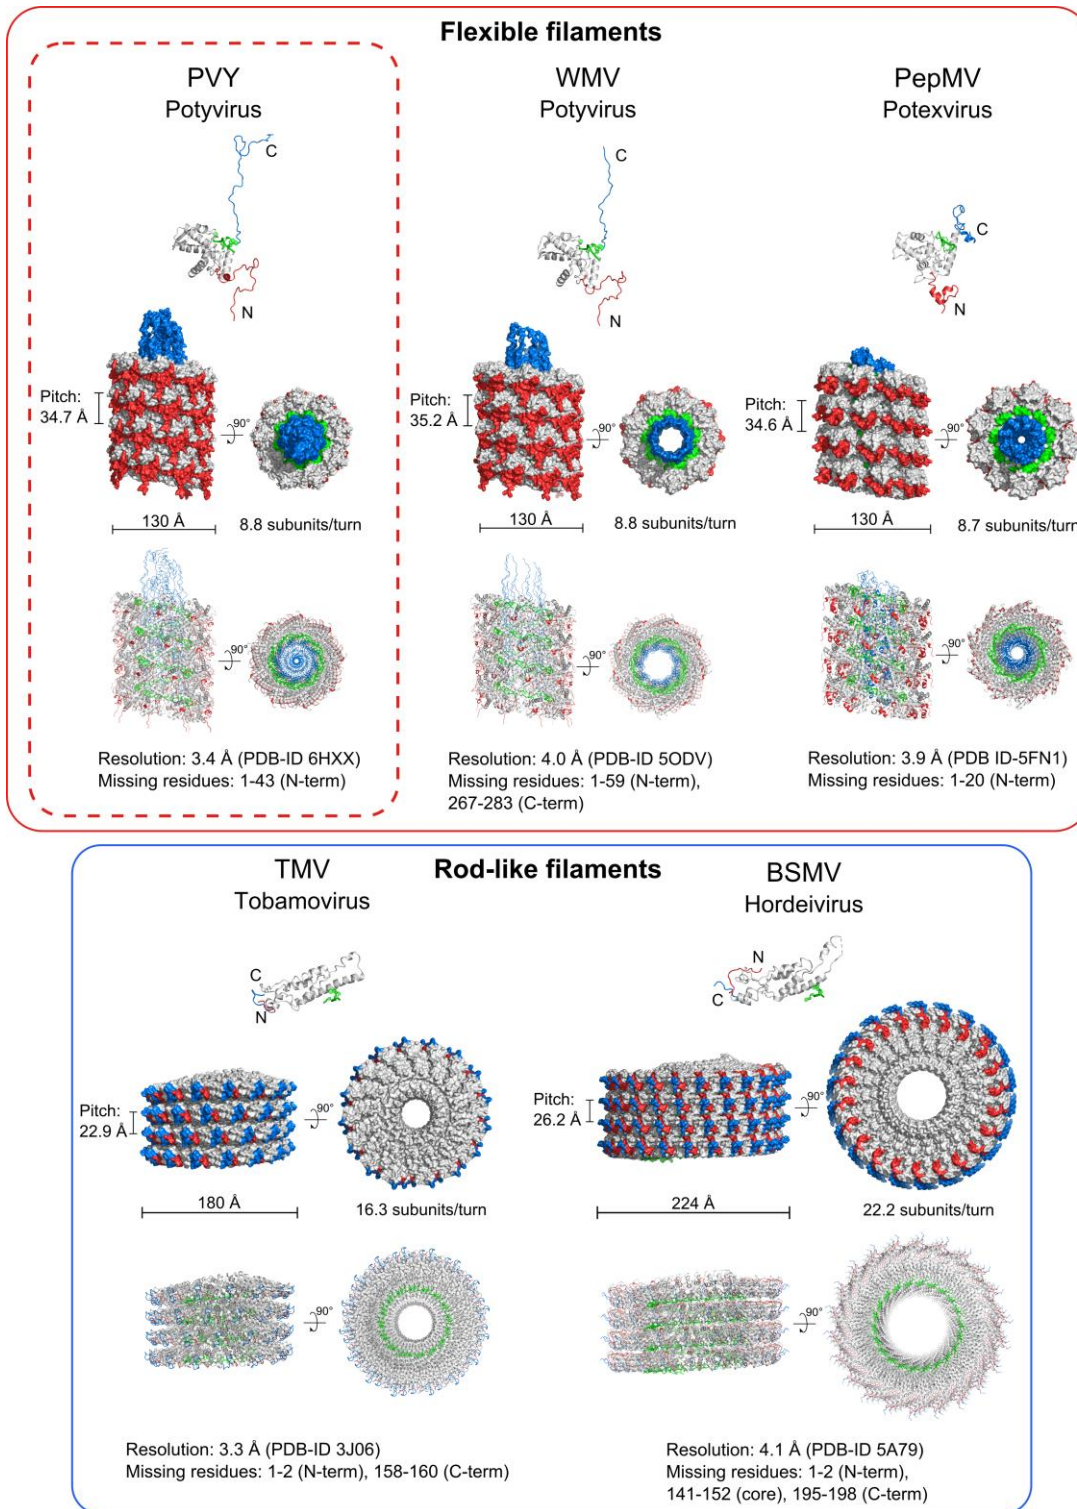

Fig. S4. Structural comparison of PVY to other filamentous viruses, flexible and rod shaped. For all viruses, the structure of a single CP unit is shown in cartoon, N-terminal region in red, core in gray, C-terminal region in blue and RNA in green color. Viral filaments are shown in surface and cartoon representation, side and top-view.

Fig. S5. Details of the PVY interaction network. Assembly of 13 interacting CP units is presented in the center of the figure. CPⁿ N-terminal region is in red, core in dark gray and C-terminal region in blue, while neighboring CPs are colored in light red (N-terminal region), yellow (core) and light blue (C-terminal region). Close-up views display specific interaction sites between CP units (red circles display interactions given by the CPⁿ N-terminal region, black circle the interactions between the cores, and blue circles show interactions given by CPⁿ C-terminal region). For clarity, some non-interacting parts were removed from the picture. The interactions between CP units are presented from CPⁿ N- to C-terminus: (A) CPⁿ – CPⁿ⁻¹⁰, (B) CPⁿ – CPⁿ⁻², (C) CPⁿ – CPⁿ⁻¹, (D) CPⁿ – CPⁿ⁻⁸ – CPⁿ⁻⁹, (E) CPⁿ – CPⁿ⁻⁸ – CPⁿ⁻⁹, (F) CPⁿ – CPⁿ⁻⁹ – CPⁿ⁺⁸ – CPⁿ⁺⁹, (G) CPⁿ – CPⁿ⁺⁸ – CPⁿ⁺⁹ – CPⁿ⁻¹, (H) CPⁿ – CPⁿ⁺¹⁷ and (I) CPⁿ – CPⁿ⁺¹ – CPⁿ⁻¹.

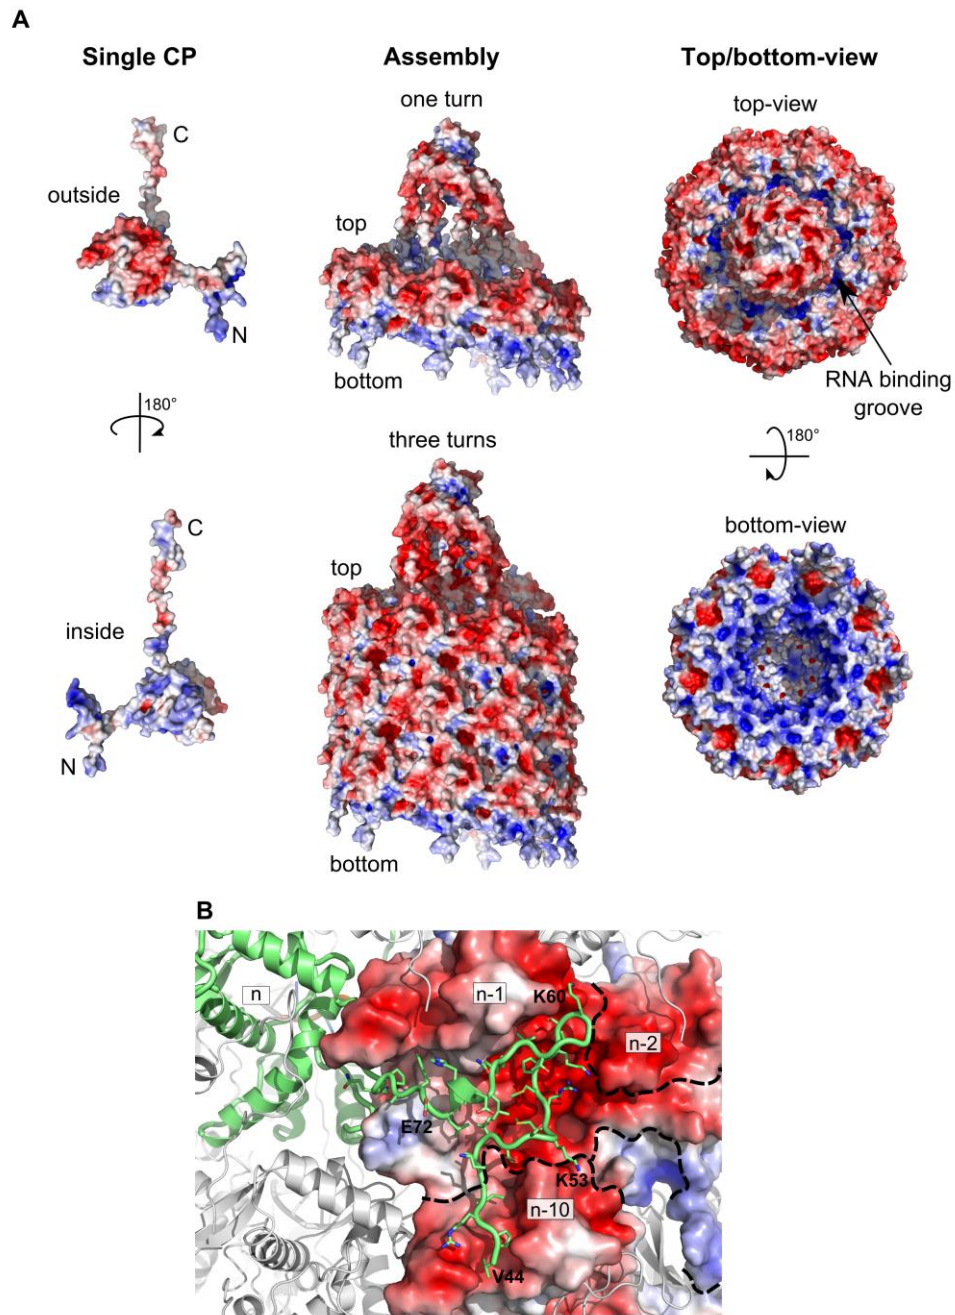

Fig. S6. Electrostatic interactions are crucial for PVY virion assembly. (A) Surface electrostatic potential (red: negative charge; blue: positive charge) of a single CP unit (left); CP units assembled into one turn (above center) and the filament (below center). Right: top- and bottom-view of the filament. The RNA-binding groove is highly positively charged to bind viral ssRNA. (B) Highly negatively charged surface of neighboring units CP^{n-1} , CP^{n-2} and CP^{n-10} promote folding of positively charged CP^n N-terminal region on their surface. The CP^n unit is shown as a green cartoon.

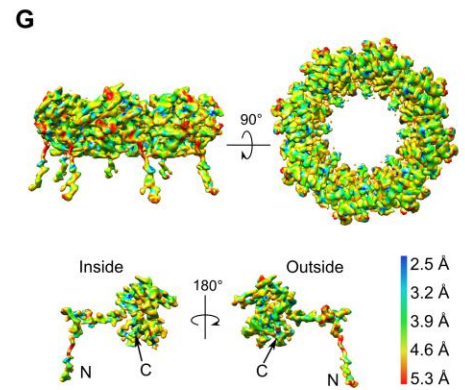

Fig. S7. Cryo-EM data collection, image processing, and model building for VLP. (A) Negative-stain TEM micrograph of VLPs. Inset: a close-up of one VLP segment. **(B)** Cryo-EM micrograph of VLPs. **(C)** Examples of VLP 2D class averages. **(D)** Sum of the power spectra obtained for 26 selected VLP segments. **(E)** Flowchart of the data collection and processing of VLP sample. **(F)** Fourier shell correlation (FSC) curves for the final reconstruction of VLP density map (above) and between VLP reconstructed model and density map (below). **(G)** Local resolution analysis of one ring extracted from VLP filament (above) and one CP unit (below), estimated using MonoRes (34). **(H)** Cryo-EM-derived atomic model of the VLP CP fit into extracted map for one CP unit. **(I)** The densities of two VLP CP segments are shown in a mesh representation with the corresponding atomic model within, showing the resolution of individual side chains (maps contoured at 5σ).

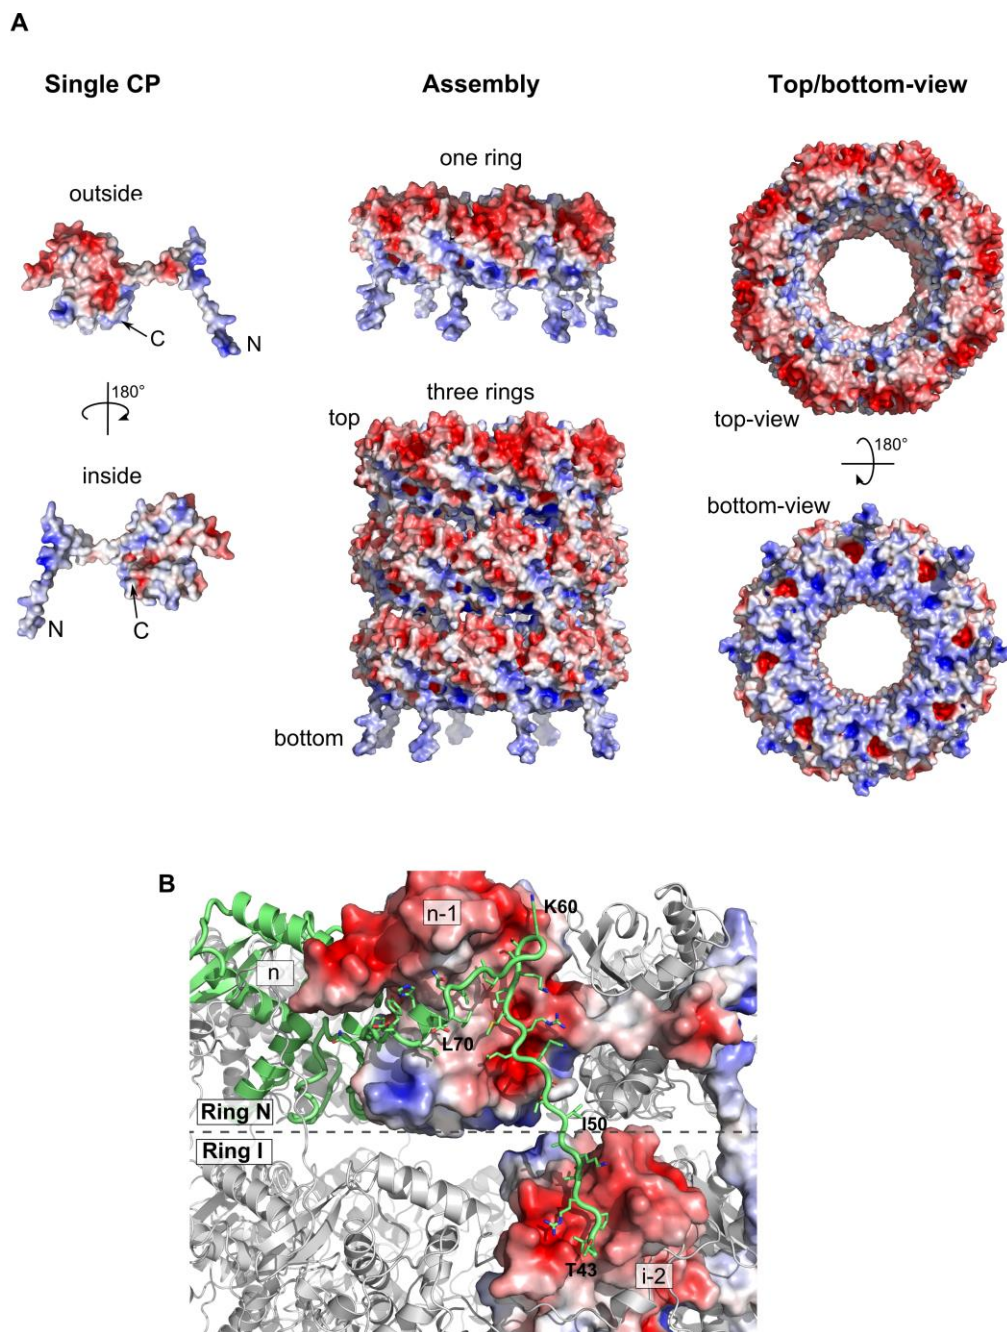

Fig. S8. Surface electrostatic potential of VLPs. (A) Surface electrostatic potential of single CP unit, views at two angles (left); CP units assembled into one ring (above center) and rings assembled into the filament (below center). Right: top- and bottom-view of the octameric ring. Red, negative charge; blue, positive charge. (B) Assembly of CP^n unit (green) with positively charged N-terminal region folding on the negatively charged surfaces of CP^{n-1} and CP^{i-2} cores.

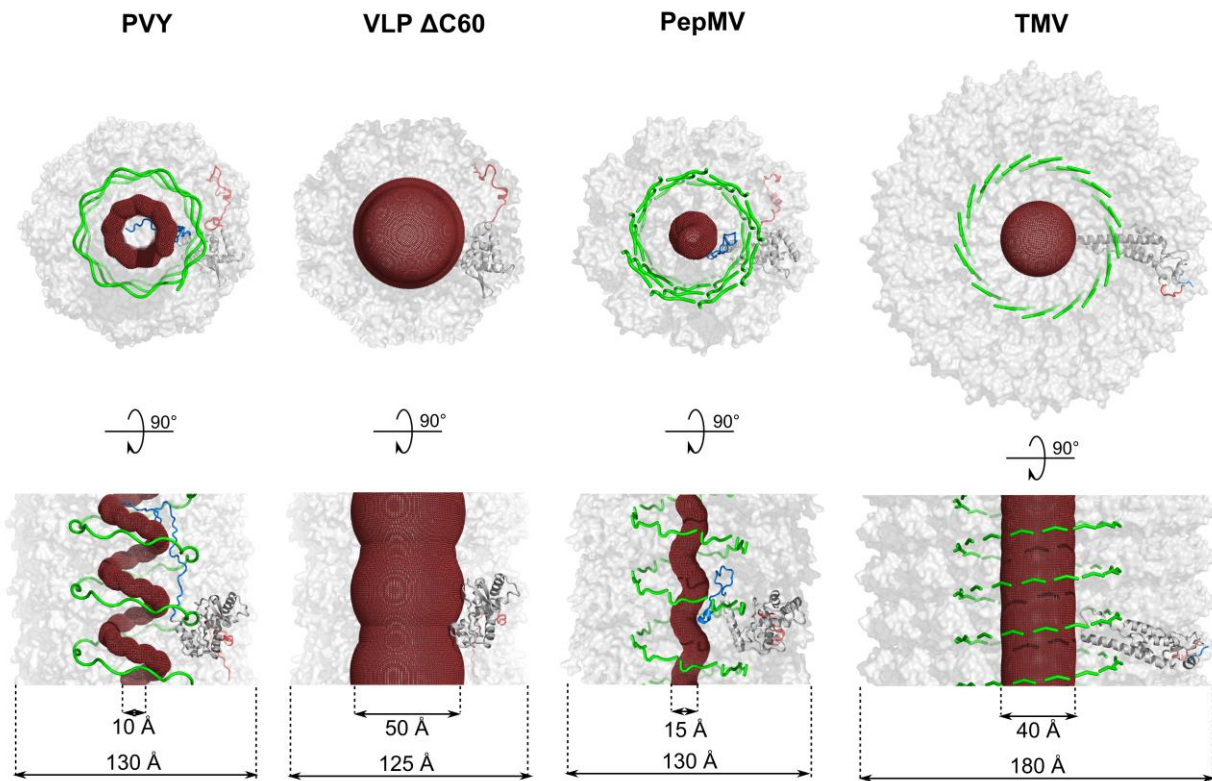

Fig. S9. Water channels in different types of filamentous particles. Differences in size and shape of the channels in potyvirus PVY, potexvirus PepMV, tobamovirus TMV and PVY VLP Δ C60 are presented as side-views and top-views. Channels (dark red dot mesh) are superimposed onto filament silhouette with one copy of CP (N-terminal region in red, core in gray, C-terminal region in blue) and RNA (green), to demonstrate particle assembly. Channels were calculated with MOLE 2.5 (<https://mole.upol.cz/>).

Table S1. Cryo-EM data collection and refinement statistics of PVY and VLP.

	PVY	VLP
Data collection		
EM equipment	FEI Titan Krios	
Voltage (kV)	300	
Detector	Falcon II	
Pixel size (Å)	1.061	
Electron dose (e ⁻ /Å ²)	48	
Defocus range (μm)	1.0-2.2	
Reconstruction		
Software	EMAN2.1, RELION 2.0 & 2.1	
Initial no. of helical segments	215,123	244,988
Final no. of helical segments	162,213	148,876
Initial model used	Geometrical model	Featureless cylinder
Symmetry	C1	C8
Helical symmetry		
Translation (Å)	3.95	42.65
Rotation (°)	-40.95	13.24
Map resolution (Å) at FSC = 0.143	3.4	4.1
Map sharpening B-factor (Å ²)	-200	-400
Model building		
Software	Coot 0.8.8	
Refinement		
Software	Phenix 1.13-2998	
Model statistics		
No. of coat protein copies	35	24
No. of residues per coat protein	224 (Val44 – Met267)	176 (Thr43 – Ile218)
No. of RNA nucleotides	175	0
Model resolution (Å) at FSC = 0.5	3.6	4.1
Validation		
Cross-correlation coefficient (CCC)	0.819	0.775
MolProbity score	1.93	1.48
Clashscore	8.18	0.37
R.m.s. deviations		
Bond length (Å)	0.008	0.009
Bond angle (°)	1.389	1.314
Ramachandran plot statistics (%)		
Preferred	91.89	86.73
Allowed	8.11	13.27
Outlier	0	0
Rotamer outliers	0.28	1.95

Table S2. Primers and probes used for in planta functional analysis of PVY mutants and their properties.*

Name	Primer and probe sequences (5' → 3')	Source	Target gene(s)	Description	Amplicon efficiency
PVY_N605	CATAGGAGAACTGAAATGCCAACT TGGCGAGGTTCCATTTCA FAM-TGATGAATGGGCTTATGGTTGGTGCA- TAMRA	this work (59) (59)	AJ390300	PVY CP	97%
COX	CGTCGCATTCCAGATTATCCA CAACTACGGATATATAAGRRCRRAACTG FAM-TGCTTACGCTGGATGGAATGCCCT- TAMRA	(60)	Sotub04g015050.1.1	cytochrome oxidase	96%

*according to MIQE (58) guidelines.

Data S1. Relative concentration of PVY RNA as measured in the leaves of *N. clevelandii* including tables S3 to S5:

Table S3. Relative concentration of PVY RNA as measured in bombarded leaves of *N. clevelandii* 7 dpb (experiment 1).

Table S4. Relative concentration of PVY RNA as measured in upper nonbombarded leaves of *N. clevelandii* 14 dpb (experiment 1).

Table S5. Relative concentration of PVY RNA as measured in bombarded leaves of *N. clevelandii* (experiment 2).
