

BMJ Open

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email info.bmjopen@bmj.com

ABSTRACT

Objective: The aim of this review was to explore the notion of alcohol-related presenteeism, i.e., whether evidence in the research literature supports an association between employee alcohol consumption and impaired work performance. **Methods:** Literature searches were performed in seven scientific databases, and in reference lists. Observational studies, published 1990 or later, in peer-reviewed scientific journals in English or a Scandinavian language, were included. Tested associations in the included studies were quality assessed, and analysed with frequency tables, cross tabulations and chi square tests of independence.

Results: Twenty-six studies, containing 132 tested associations, met the eligibility criteria. The vast majority of tested associations (77 %) indicated that higher levels of alcohol consumption were associated with higher levels of impaired work performance, and these positive associations were considerably more likely than negative associations to be statistically significant. Alcohol exposure measured by hangover episodes and composite instruments were overrepresented among significant positive associations of moderate and high quality. Overall, 61 % of the tested associations were characterised by low quality.

Implications: Workplace interventions aimed at improving employee productivity and health could benefit from integrating an awareness of a possible relationship between alcohol consumption and impaired work performance. **Conclusions:** Evidence does provide some support for the notion of alcohol-related presenteeism. However, due to low research quality and lack of longitudinal designs, evidence should be characterised as inconclusive. More robust and less heterogeneous research is warranted.

Key words: Alcohol consumption; Presenteeism; Work performance; Sick leave; Employees; Workplace interventions; Workplace health promotion

Strengths and limitations of this study

- To the best of our knowledge, this is the first systematic review to exclusively explore evidence for the notion of alcohol-related presenteeism, i.e., whether evidence supports a possible association between alcohol consumption and impaired work performance.
- Twenty-six studies from 15 countries, containing 132 tested associations between alcohol consumption and work performance, met the eligibility criteria. The majority of tested associations indicated that higher levels of alcohol consumption were associated with impaired work performance. However, evidence was largely characterised by low quality and a large number of associations not reaching statistical significance.
- Due to the heterogeneous nature of the included data, we were not able to conduct meta-analyses.
- Future research on alcohol-related presenteeism should utilise more robust study designs, include potential mediating and moderating variables, and employ measurement instruments with satisfactory psychometric properties.

INTRODUCTION

Alcohol consumption

Excessive alcohol consumption is a major risk factor for disease, disability and mortality, and has been identified as a causal agent in more than 200 disease and injury conditions.[1] Higher alcohol consumption has been found to be associated with lowered life expectancy,[2] and, according to the World Health Organization,[3] harmful alcohol consumption is related to approximately three million annual deaths globally. Among the population aged 15 to 49 years, alcohol has been identified as the leading risk factor for death and disability-adjusted life-years.[4] Alcohol is by far the most used and misused psychoactive substance in the workforce,[5] and one to three out of ten employees can be characterised as risky drinkers in need for interventions,[6-9] i.e., having a consumption pattern that increases the risk for social-, legal-, medical-, occupational-, domestic- and economic problems.[10]

Alcohol can affect mood as well as cognitive and psychomotor performance. Psychopharmacological and experimental workplace simulation studies have explored effects of alcohol intoxication on performance, generally suggesting little consistent impairment at low to moderate intoxication levels (blood alcohol content (BAC) 0.01 % - 0.08 %), while at higher BAC levels (≥ 0.09 %) impairment seems to increase quite linearly with task complexity.[11-14] Hangover episodes, i.e., an adverse mental and physical state experienced after heavy drinking when the BAC level returns to zero,[5, p. 85] include symptoms that may be related to performance decrements, such as headache, nausea, drowsiness, and sensitivity to light/sound.[12, 15, 16]

Alcohol consumption may influence activity performance in a variety of domains, including the occupational sphere. Regarding employees' alcohol consumption, one may distinguish between workforce overall alcohol consumption (consumption regardless of context) and work-related alcohol consumption (consumption prior to or during the workday,

1
2
3 as well as in contexts directly related to the work environment or the employment
4
5 relationship).[5, 17-19] According to Frone's integrative conceptual model of employee
6
7 substance use and productivity, not showing up at work (absenteeism) and arriving late at
8
9 work (tardiness) are primarily believed to be affected by off-the-job drinking, while leaving
10
11 work early and reduced work performance are thought mainly to be due to on-the-job
12
13 drinking.[5, 20] However, the model does allow for possible cross-over effects between
14
15 contexts. Off-the-job drinking "may indirectly affect performance outcomes to the extent that
16
17 it causes off-the-job substance impairment, which when carried into the workplace becomes
18
19 workplace impairment".[5, p.134] An association between employees' alcohol consumption
20
21 and absenteeism is quite well established in the literature, e.g.,[21], while alcohol-related
22
23 presenteeism stand out as a far more under-researched topic.
24
25
26
27
28
29
30

31 **Presenteeism**

32
33 Presenteeism has been defined in a variety of ways and the concept somewhat suffers from
34
35 a "definitional creep".[22, p.521] Two distinct traditions in presenteeism research have been
36
37 identified.[22, 23] The first tradition has primarily emphasised the exploration of
38
39 presenteeism determinants and studied presenteeism as a chosen behaviour or personal
40
41 choice. In this perspective, presenteeism is defined as the act of "showing up for work even
42
43 when one is ill",[22, p.519] or "the phenomenon of people who, despite complaints and ill
44
45 health that should prompt rest and absence from work, are still turning up at their jobs".[24,
46
47 p.503] Hence, presenteeism may be conceived as an alternative to absenteeism and, as such,
48
49 even as a health-promoting measure within a return to work framework.[25] The second
50
51 tradition has been more oriented towards consequences of this behaviour, in particular related
52
53 to productivity loss. Researchers in this tradition have defined presenteeism as "decreased on-
54
55 the-job performance due to the presence of health problems",[26, p.548] "the health-related
56
57
58
59
60

1
2
3 productivity loss while at paid work",[27, p. 351] or "the measurable extent to which health
4 symptoms, conditions and diseases adversely affect the work productivity of individuals who
5 choose to remain at work".[28, p. 2] Evidently, the first tradition treats presenteeism as a
6 behaviour, regardless of its consequences, while the second tradition claims that adverse
7 performance outcomes are inherent in the conceptualisation of presenteeism.
8
9
10
11
12
13

14 It is plausible to conceive that a variety of health conditions do not result in productivity
15 impairment and, in an organisational perspective, it may be argued that situations in which
16 employees attend work while sick become of interest primarily when performance decrements
17 are involved. In this systematic review, we understand presenteeism as reduced on-the-job
18 performance due to health problems.[26] As such, presenteeism constitutes a link between on-
19 the-job productivity and employee health,[26] addressing the grey area between optimal work
20 performance and the absence of productivity (i.e., absenteeism).[22] Within this frame,
21 alcohol-related presenteeism can be conceptualised as the presence of a positive association
22 between alcohol consumption and impaired work performance (or conversely as a negative
23 association between alcohol consumption and work performance). Alcohol-related
24 presenteeism is thus operationalised as the product of a relationship between two variables
25 (exposure: alcohol consumption, outcome: work performance) rather than a single variable
26 (attending work while sick), rendering it possible to retain the notion of work performance as
27 inherent in the phenomenon of presenteeism without conflating cause and effect.

33
34
35
36
37
38
39
40
41
42
43
44
45

46 Absenteeism and presenteeism have been found to be moderately correlated, and related by
47 baseline presenteeism being a risk factor for future absenteeism.[29] Several authors have
48 argued that presenteeism may carry more substantial societal costs than absenteeism. Hemp
49 stated that "the illnesses people take with them to work (...) usually account for a greater loss
50 in productivity because they are so prevalent, so often go untreated, and typically occur
51
52
53
54
55
56
57
58
59
60

1
2
3 during peak working years. Those indirect costs have long been largely invisible to
4
5 employers".[30, p. 2]
6

7
8 Known predictors of presenteeism include diseases and disorders (e.g., musculoskeletal
9
10 problems, depression and anxiety), certain individual characteristics (e.g., gender, age, job
11
12 satisfaction, stress and family status), and factors related to the organisational environment
13
14 (e.g., employment security, work schedules, workload, managerial support, corporate culture
15
16 and leadership style).[23] Knowledge of mechanisms underlying presenteeism is, however,
17
18 still quite limited. In particular, the impact of individual health risks or combinations of risks
19
20 should be researched more extensively.[26]
21
22
23
24
25

26 **Rationale and aim**

27
28 Some studies have explored alcohol-related presenteeism, either directly or indirectly.
29
30 There is, however, a lack of synthesised knowledge, rendering it difficult to assess the
31
32 evidence of a possible association between employee alcohol consumption and work
33
34 performance. In their review of relationships between psychological, physical and behavioural
35
36 health and work performance, Ford et al. found alcohol consumption to be weakly associated
37
38 with work performance problems.[31] However, this conclusion was based solely on 12
39
40 studies identified in two scientific databases in 2011. It seems imperative to generate new
41
42 accumulated knowledge in order to aid in deciding whether and how workplace interventions
43
44 and Workplace Health Promotion Programs (WHPP) should include an emphasis on alcohol
45
46 consumption.
47
48
49

50
51 The aim of this review was to explore whether evidence in the research literature supports
52
53 the notion of alcohol-related presenteeism, i.e., whether evidence supports an association
54
55 between alcohol consumption and impaired work performance.

METHODS

Protocol and registration

This review is registered in the International prospective register of systematic reviews (PROSPERO, ID: CRD42017059620), and is part of the Norwegian national WIRUS project (Workplace Interventions preventing Risky Use of alcohol and Sick leave). Original research from the WIRUS project is published elsewhere.[9, 19, 32]

Eligibility criteria

Studies exploring alcohol-related presenteeism, i.e., the relationship between alcohol consumption (exposure) and work performance (outcome) among employees (population) were included in this review. Included studies had to satisfy the following criteria: (i) *type of study* (observational study, e.g., case-control, prospective cohort or cross-sectional study); (ii) *type of participants* (the study reported results from a sample of employees, defined as all salaried persons between 16 and 70 years of age, both workers and managers, regardless of employment sector or branch); (iii) *type of measures/tests* (the study reported one or more statistical test(s) of a relationship between a measure of alcohol consumption and a measure of work performance); (iv) *type of publication and language* (the study was reported as a full text empirical research article published in English or a Scandinavian language in a peer-reviewed scientific journal); and (v) *time* (the study was published year 1990 or later).

Studies were excluded if they (i) reported results from samples in which employees were mixed with other groups (e.g., full-time students, unemployed), unless results were reported independently for each group, and/or (ii) reported tests where alcohol and/or work performance were analysed in combination with other factors (e.g., if on-the-job performance was analysed in combination with absenteeism within a wider productivity variable).

Literature search

A primary database search strategy (based on a Medline structure) was developed and applied in seven scientific databases (Medline; Web of Science; PsycINFO; Cinahl; Amed; Embase; Swemed+). Where necessary, the search strategy was adapted to each database. The primary (Medline) strategy comprised a total of 29 steps, of which 18 were abstract-level text searches, 7 were based on MeSH terms (Medical Subject Headings, Topics, or similar terms), and the remaining were combinations of results applying Boolean operators (OR; AND). First, studies relating to the population (employees) were searched for (employee*; employed; worker*; workforce; work [MeSH]; employment [MeSH]), followed by studies relating to the exposure (alcohol consumption) (alcohol*; drink*; drunk*; hangover; "hang over"; alcohol drinking [MeSH]; binge drinking [MeSH]; drinking behavior [MeSH]), and the outcome (work performance) (presenteeism; "job productiv*"; "work productiv*"; "job capacity"; "work capacity"; "job ability"; "work ability"; "job impair*"; "work impair*"; presenteeism [MeSH]; work performance [MeSH]). Finally, search blocks for population, exposure and outcome were combined.

No restrictions were imposed at the search stage. The primary search strategy was pilot tested by three reviewers prior to conducting the main searches. Databases were initially searched in September 2017. An updated search was conducted in October 2018. Additionally, reference lists in included studies were hand searched for potential relevant studies.

Study and data selection

After searching the seven databases, hand searching in reference lists in included studies and removing duplicates, identified studies were screened for relevance on a title/abstract level. For quality assurance of the search strategy and eligibility criteria, the first 20 studies

1
2
3 were independently screened by three reviewers. The remaining studies were independently
4 screened by two reviewers. Initial disagreements on eligibility were resolved through
5 discussion. The reviewers reached consensus. Hence, it was not necessary to consult with a
6 third reviewer. Potentially relevant studies were independently assessed in full text format for
7 eligibility by two reviewers. Initial disagreements were resolved through discussion, without
8 the need for consulting a third reviewer.
9

10
11
12 Data from the included studies (study characteristics and outcome data) were extracted
13 independently by two reviewers by utilising data extraction forms. Disagreements were
14 resolved through discussion, without the need to consult a third reviewer.
15
16

17 **Quality assessment**

18
19
20 Searches indicated that studies fulfilling the inclusion criteria were characterised by
21 different designs, and by containing several statistical associations between alcohol
22 consumption and presenteeism. Included studies were characterised by exploring broader
23 aims related to health and productivity, while this review emphasises the relationship between
24 alcohol and work performance in particular. Hence, it was deemed inappropriate to conduct
25 overall quality assessment of each study. Instead, relevant tested associations in the included
26 studies were assessed on two key domains: (i) sample size (low quality = <500; moderate
27 quality = 500-999; high quality = ≥ 1000), and (ii) risk of confounding (level of adjustment:
28 low quality = unadjusted or unclear; moderate quality = adjusted for individual *or* work-
29 related/environmental factor(s); high quality = adjusted for individual *and* work-
30 related/environmental factors). Each association was ascribed an overall quality judgement
31 (low, moderate or high) based on the assessment of the two key domains, according to the
32 "worst score counts" algorithm recommended by the COSMIN guidelines.[33] Hence, an
33 association's overall score was equal to its lowest domain assessment. High-quality
34
35
36
37

3 associations were thus characterised by being based on at least 1000 observations and being
4
5 adjusted for individual (e.g., gender; age; personality; disease conditions; drug use) as well as
6
7 work-related/environmental factors (e.g., work position; work schedule; job characteristics).
8
9

10 The quality assessment procedure was pilot tested on a random sample of 10 associations.
11
12 Quality assessments were performed independently by two reviewers. Consensus was reached
13
14 and initial disagreements were resolved through discussion, without the need for consulting a
15
16 third reviewer.
17
18
19
20
21

22 **Analysis**

23
24 Measures of exposure (alcohol consumption) as well as measures of outcome (work
25
26 performance) displayed considerable heterogeneity between the included studies. As a result
27
28 of the heterogeneous nature of the included data, meta-analyses were deemed inappropriate.
29
30 Included data (associations) were instead analysed with frequency tables and cross
31
32 tabulations. First, associations were sorted into a frequency table by quality level and overall
33
34 association characteristics. Next, four contingency tables were constructed in order to explore
35
36 properties of the identified associations more thoroughly: (i) direction and significance, (ii)
37
38 quality and direction, (iii) publication year and quality, and (iv) significance and quality. The
39
40 four 2x2 tables were analysed by means of odds ratios (with 95 % confidence intervals) and
41
42 chi square tests of independence (with phi coefficients). Finally, measurements of alcohol
43
44 consumption and work performance applied in the included studies were categorised into
45
46 subgroups.

55

56 **Patient and public involvement**

57
58
59 No patients or public were involved in this review study.
60

RESULTS

Overview of the evidence

Searches in the seven databases resulted in 540 articles (Medline: n = 135; Web of Science: n = 128; PsycINFO: n = 63; Cinahl: n = 22; Amed: n = 3; Embase: n = 189; Swemed+: n = 0). Hand searching in reference lists resulted in an additional nine articles. After duplicate removal (n = 282), a total of 267 unique articles remained. Application of the eligibility criteria resulted in exclusion of 158 studies, leaving 109 potentially relevant articles.

Eighty-three studies were excluded after being subjected to full text assessment. The vast majority of these were excluded as a result of not reporting a statistical test of an association between alcohol consumption and work performance (n = 52), or because of publication type (n = 24). Articles not reporting tests of associations were typically characterised by (i) not studying variables that conceptually could be defined as alcohol consumption and/or work performance, and (ii) analysing alcohol consumption and/or work performance in combination with other factors, rendering it impossible to isolate the association of interest. Alcohol being analysed in combination with smoking/other lifestyle factors, and work performance being analysed in combination with absenteeism constitute typical examples. Articles excluded on the basis of publication type were typically conference papers. The study selection process resulted in 26 studies satisfying all inclusion criteria, and is presented in Figure 1.

[Figure 1 about here]

1
2
3 The 26 included studies were based on data from 92 730 employees from a total of 15
4 countries (Australia, China, Czech republic, Denmark, Finland, Greece, Ireland, Japan, the
5 Netherlands, Norway, Portugal, Slovenia, Sweden, Switzerland and the USA). Employees in
6 the USA constituted the samples in half of the studies (13 of 26). The vast majority of studies
7 (21 of 26) were based on cross-sectional research designs. A total of 132 associations between
8 alcohol consumption and work performance were tested in the 26 included studies.
9
10 Characteristics of the included studies are presented in Table 1. Characteristics of the included
11 associations are presented in Supplementary File 1.

Quality of the included data

Ninety-three of the 132 associations (71 %) were based on samples smaller than 1000 employees. Approximately half of the associations were unadjusted ($n = 63$; 48 %), while 29 associations (22 %) were adjusted for individual factors as well as for work-related/environmental factors. By applying the "worst score counts" algorithm, 80 associations (61 %) were judged as being of low quality, 38 associations (29 %) were of moderate quality, while 14 associations (11 %) were characterised by high quality. Results from quality assessment of the included associations are presented in Supplementary File 2.

Direction, significance, quality and time

One-hundred-two of the 132 tested associations (77 %) indicated a positive relationship between alcohol consumption and work performance, i.e., implying that higher levels of consumption were associated with higher levels of performance impairment. Approximately half of these ($n = 56$, 55 %) were statistically significant. The majority of positive associations was judged to be of low quality ($n = 70$, 69 %), followed by moderate ($n = 23$, 22 %) and high quality ($n = 9$, 9 %).

Twenty-five of the 132 tested associations (19 %) indicated a negative relationship, i.e., implying that higher levels of alcohol consumption were associated with lower performance impairment (higher work performance). Only two of these associations were statistically significant, and both of these were of low quality. These two associations (ID66 and ID68, in Friedman *et al.*[49]) tested the relationship between duration of alcohol use and overall work performance, and found that longer duration, as opposed to shorter duration, was associated with higher work performance.

Five associations (4 %) were not possible to classify as either positive or negative. They were characterised by (i) finding no differences in work performance between compared

1
2
3 alcohol consumption groups (ID102 in Moore *et al.*[55]; ID130 in van den Berg *et al.*[57]);
4
5 (ii) by finding significant differences between multiple consumption groups, but without a
6
7 consistent positive/negative pattern (ID28 and ID29 in Kim *et al.*[39]); or (iii) by finding a J-
8
9 shaped pattern where abstainers scored comparable to moderate-level drinkers on impaired
10
11 performance (i.e., higher than low-level drinkers), but still lower than heavy drinkers (ID98 in
12
13 Moore *et al.*[55]). The identified associations, sorted by quality level and overall association
14
15 characteristics, are presented in Table 2.

High	[36],[37],[38],[41],[127]		[70],[71],[72],[126]	[85],[86],[87],[88],[89]	

Note. Number in brackets = association ID; ^a Higher level of alcohol associated with higher level of presenteeism; ^b Lower level of alcohol associated with higher level of presenteeism, or higher level of alcohol associated with lower level of presenteeism; ^c Inconsistent direction, no relationship or J-shaped relationship between alcohol and presenteeism

1
2
3 Positive associations were considerably more likely than negative associations to be
4 statistically significant (OR = 14.00, 95 % CI: 3.1 – 65.5; χ^2 (1, n = 127) = 17.80, p = .000, ϕ
5 = .37). On the other hand, negative associations were less likely than positive associations to
6 be of low quality (OR = 0.22, 95 % CI: 0.1 – 0.6; χ^2 (1, n = 127) = 11.37, p = .001, ϕ = -.30).
7
8 Furthermore, recent studies (\geq year 2000) were more likely than older studies ($<$ year 2000) to
9 be of moderate or high quality (OR = 2.95, 95 % CI: 1.30 – 6.79; χ^2 (1, n = 132) = 6.96, p
10 = .008, ϕ = .23). There was no significant relationship between whether associations were
11 significant and whether they were of moderate/high or low quality. The four 2x2 contingency
12 tables are presented in Table 3.

OR = odds ratio, with 95% confidence interval; χ^2 = chi square test of independence, with phi coefficient; ** $p < .01$; *** $p < .001$; ns = non-significant

Measurements of alcohol consumption and work performance

Categorisation of the applied measurements of alcohol consumption in the 26 included studies revealed eight subgroups: (i) consumption status (e.g., current alcohol drinker (yes/no), applied in Yu *et al.*[48]); (ii) drinking frequency (e.g., number of times drunk during past three months, applied in Ames *et al.*[17]; typical frequency of alcohol consumption during past year, applied in Aas *et al.*[32]); (iii) drinking intensity (e.g., average number of alcohol drinks during the past week, applied in Adler *et al.*[34]); (iv) drinking volume (e.g., monthly frequency x typical quantity during past 30 days, applied in Blum *et al.*[51]); (v) binge drinking (e.g., binge drinking (6 or more drinks on a single occasion) frequency during past year, applied in Aas *et al.*[32]); (vi) hangover (e.g., frequency of hangover episodes at work during past year, applied in Ames *et al.*[17]); (vii) composite instruments comprising several aspects of consumption, such as frequency, intensity and alcohol problems (e.g., the Alcohol Use Disorders Identification Test,[10] applied in Richmond *et al.*[43]); and (viii) alcohol-related diagnosis (e.g., DSM-IV diagnosis of alcohol abuse, applied in Lim *et al.*[53]).

The 26 included studies contained a total of six work performance measurement categories: (i) overall work performance/impairment (e.g., supervisor ratings of overall work performance, applied in Lowmaster *et al.*[54]; self-reported current work performance compared to lifetime best, applied in Furu *et al.*[56]; Work Limitations Questionnaire sum score,[58] applied in Kirkham *et al.*[40]); (ii) domain-specific work performance/impairment (e.g., Work Limitations Questionnaire subscale Time management,[58] applied in Adler *et al.*[34]); (iii) impaired performance quantity (e.g., number of days working below a normal level of performance during past 12 months, applied in Fisher *et al.*[36]; estimated percent impaired performance during past week, applied in Boles *et al.*[50]); (iv) impaired performance frequency (e.g., frequency of impaired performance episodes during past 12

1
2
3 months, applied in Schou *et al.*[44]); (v) prognosis of work performance (e.g., self-assessed
4 probability of good work performance within frame of 6 months, applied in Karlsson *et*
5 *al.*[37]); and (vi) work performance status (e.g., impaired work performance during past 4
6 weeks (yes/no), applied in Yu *et al.*[48]). The identified associations, sorted according to
7 measurements of alcohol consumption and work performance, are presented in Table 4.

1
2
3 1 In the 132 included associations, the most frequently applied alcohol measurement was
4
5 2 drinking intensity (n = 28, 21 %) and composite instruments (n = 27, 20 %). Overall work
6
7 3 performance/impairment (n = 67, 51 %) and quantity of impaired performance (n = 35, 27 %)
8
9 4 were the most frequently utilised work performance measures. When exploring the group of
10
11 5 associations characterised by being significant positive and of moderate or high quality (n =
12
13 6 18), the vast majority of these (n = 15) applied either hangover (n = 9) or composite
14
15 7 instruments (n = 6) as alcohol consumption measures.

9 DISCUSSION

10 The aim of this review was to explore whether evidence in the research literature supports
11 the notion of alcohol-related presenteeism, i.e., whether evidence supports an association
12 between employee alcohol consumption and work performance. Twenty-six studies,
13 containing a total of 132 tested associations between alcohol consumption and presenteeism,
14 based on data from 92 730 employees in 15 countries, met the eligibility criteria.

15 The vast majority of the associations (102 of 132, 77 %) indicated a positive relationship
16 between alcohol consumption and impaired work performance, i.e., implying that higher
17 levels of alcohol consumption were associated with higher levels of impaired performance.
18 Furthermore, positive associations were considerably more likely than negative associations
19 to be statistically significant. Among the included studies in this review, positive associations
20 between alcohol consumption and impaired work performance were identified in a variety of
21 employee samples, e.g., computer manufacturer employees in the USA (Kirkham *et al.*[40]),
22 Finnish employees with multisite pain in various occupations (Pensola *et al.*[42]), Japanese
23 community workers (Tsuchiya *et al.*[46]), and manufacturing plant employees in the USA
24 (Ames *et al.*[17]).

1
2
3 1 Alcohol use has the potential for influencing cognitive and psychomotor performance,
4
5 2 which may explain why employees' alcohol consumption is associated with work
6
7 3 performance. In particular, hangover episodes are characterised by symptoms that can induce
8
9 4 work impairments (headache, nausea, drowsiness etc.),[12, 15, 16] and alcohol intoxication,
10
11 5 at least at higher blood alcohol content, may produce work impairments that increase linearly
12
13 6 with task complexity.[11-14] Positive associations between alcohol consumption and
14
15 7 performance impairments are not so surprising in light of knowledge on the relationship
16
17 8 between alcohol consumption and absenteeism. In their review, Schou and Moan found that
18
19 9 employees' consumption was positively associated with both short-term and long-term sick
20
21 10 leave.[21] The complementary hypothesis of the relationship between absenteeism and
22
23 11 presenteeism claims that these behaviours are both related to employees' overall health status
24
25 12 and that they are positively associated.[23] Research has demonstrated moderate positive
26
27 13 correlations between absenteeism and presenteeism and that presenteeism may be a risk factor
28
29 14 for future absenteeism.[23, 29]

30
31
32
33
34
35 15 Alcohol measurements based on hangovers and composite instruments were
36
37 16 overrepresented in associations characterised by being significant positive and of moderate or
38
39 17 high quality. Hangovers tend to result from binge drinking episodes, or drinking shortly
40
41 18 before work. Such short-term impairment-producing consumption may be more predictive of
42
43 19 work impairments than for instance typical drinking frequency, which instead may be more
44
45 20 predictive of long-term ill-health consequences.[59] Composite instruments, such as the
46
47 21 Alcohol Disorders Identification Test,[10] tend to assume a more complex relationship
48
49 22 between alcohol, health and performance than what may be the case for more basic
50
51 23 measurements (e.g., drinking frequency or intensity). Hence, a composite instrument
52
53 24 measuring both consumption and experienced alcohol problems may be more predictive of
54
55 25 productivity outcomes such as work performance.

1
2
3 1 However, the majority of positive associations were judged to be of low quality, and 25 of
4
5 2 132 associations (19 %) even indicated a negative relationship, i.e., implying that higher
6
7 3 levels of alcohol consumption were associated with lower performance impairments (higher
8
9 4 performance). Moreover, five associations were inconsistent, i.e., not possible to classify as
10
11 5 positive or negative, or did not reveal any association between alcohol consumption and work
12
13 6 performance at all. Negative associations were less likely than positive associations to be of
14
15 7 low quality.

18
19 8 The relationship between alcohol consumption and health outcomes has, in some studies,
20
21 9 been described as a J-shaped curve where low to moderate consumption is associated with
22
23 10 better health outcomes than non-drinking.[60] In their study of manufacturing company
24
25 11 employees in the USA, Moore et al. found a J-shaped relationship between alcohol
26
27 12 consumption and percentage of time at work spent goofing off.[55] In this study, abstainers
28
29 13 scored higher on goof-off time than low-moderate drinkers but lower than heavy drinkers. It
30
31 14 is, however, somewhat unclear whether low-moderate levels of alcohol consumption in fact
32
33 15 have some protective effects or whether such findings are products of confounding.[4, 60, 61]
34
35 16 Nevertheless, potential curvilinear relationships between alcohol consumption and health
36
37 17 outcomes may contribute to explain why a considerable proportion of associations failed to
38
39 18 demonstrate significant positive relationships. Moreover, on-the-job performance outcomes
40
41 19 may be more directly affected by on-the-job drinking than by off-the-job drinking, even
42
43 20 though off-the-job consumption may translate into workplace impairment.[5] Among the
44
45 21 studies included in this review, only one (Ames *et al.*[17]) contained explicit measures of on-
46
47 22 the-job drinking, while the remaining studies measured overall consumption (consumption
48
49 23 regardless of context). Moreover, overall consumption may have differential impact on
50
51 24 different domains. In a study of employees in Norway, Aas *et al.*[32] found that overall
52
53 25 consumption demonstrated stronger associations with performance impairments outside the
54
55
56
57
58
59
60

1
2
3 1 workplace compared to work performance, which may be due to employees moderating (self-
4
5 2 regulating) their behaviour at work as a result of potential sanctions from employers. Self-
6
7 3 regulatory motivations and mechanisms may contribute to hide alcohol-related presenteeism,
8
9 4 which may complicate the exploration of associations between alcohol consumption and work
10
11 5 performance.
12
13
14
15
16

17 **Implications**

18
19 8 Overall, this review does provide some support for the notion of alcohol-related
20
21 9 presenteeism, i.e., that employee alcohol consumption may be associated with performance
22
23 10 decrements at work. Workplace interventions aimed at improving employee productivity and
24
25 11 health could benefit from integrating an awareness of such a possible relationship.
26
27

28 12 However, it is not possible to draw firm conclusions regarding the relationship between
29
30 13 alcohol consumption and work performance. Based on research identified in this review, one
31
32 14 cannot plausibly conclude that alcohol consumption constitutes a risk factor for impaired
33
34 15 work performance. The majority of identified evidence was of low quality as a result of low
35
36 16 power (small sample sizes) and/or risk of confounding. Moreover, the majority of identified
37
38 17 studies were cross-sectional, and thereby unable to draw causal inferences about the
39
40 18 relationship between exposure and outcome. Above all, this review implies the need for
41
42 19 further research. First, future research would benefit from studying alcohol-related
43
44 20 presenteeism by means of more robust study designs that better enable exploration of causal
45
46 21 mechanisms (e.g., case-control and cohort studies), as well as by including potential
47
48 22 mediating and moderating variables. Second, both alcohol consumption and presenteeism are
49
50 23 conceptualised and measured very differently across studies. Such heterogeneity makes it
51
52 24 difficult to explore findings in the literature by means of meta-analyses. Progress in the field
53
54 25 seems to hinge on researchers' ability to reach more agreement on how to conceptualise these
55
56
57
58
59
60

1 variables and measure them by utilising instruments with satisfactory psychometric
2 properties. This seems particularly true for the concept of presenteeism. According to an
3 expert panel from the American College of Occupational and Environmental Medicine,[27, p.
4 351] productivity instruments should be supported by scientific evidence, be applicable to the
5 specific work setting, support decision making, and be practical. Based on their review of
6 measurement properties and quality of presenteeism instruments, Ospina *et al.*[62] concluded
7 that the following three instruments were most strongly supported by evidence: The Stanford
8 Presenteeism Scale (6-item version;[63]), the Endicott Work Productivity Scale (EWPS;[64]),
9 and the Health and Work Questionnaire (HWQ;[65]). Regarding measurement of alcohol
10 consumption, future research could benefit from differentiating between overall consumption
11 (e.g., measured with a composite instrument such as the Alcohol Use Disorders Identification
12 Test;[10]), hangover episodes, on-the-job drinking and off-the-job drinking. By employing
13 such distinctions, researchers would be better able to explore a potential correspondence
14 between consumption contexts, impairment contexts and performance outcomes.[5, 20]

16 **Methodological considerations**

17 This review has some limitations. First and foremost, due to the heterogeneous nature of
18 the identified data, we were unable to perform meta-analyses on the included data.

19 Second, it may be considered a limitation that this review utilised associations and not
20 studies as the unit of interest. Associations were deemed the appropriate unit of interest in this
21 review for two reasons: (i) included studies were characterised by exploring broader aims
22 related to health and productivity, while this review specifically aimed at exploring the
23 relationship between alcohol consumption and work performance, and (ii) in several studies,
24 multiple associations between alcohol consumption and work performance were tested (often
25 with different measures and subgroups within each study).

1
2
3 1 Third, this review did not utilise a previously validated critical appraisal tool (CAT) for
4
5 2 assessment of included primary research. One reason for this is that studies based on different
6
7 3 study designs were included in the review. At present, there exists no generic gold standard
8
9 4 CAT for application across study designs.[66, 67] A second reason is that the current review
10
11 5 emphasised associations rather than studies as the unit of interest. Hence, it was deemed more
12
13 6 appropriate to develop a parsimonious and conservative quality assessment system in which
14
15 7 each association was evaluated based on power (sample size) and risk of confounding (level
16
17 8 of adjustment). Deliberately, we chose a conservative approach to quality assessment by
18
19 9 ascribing each association an overall score in accordance with the "worst score counts"
20
21 10 algorithm. Such an approach is in line with the COSMIN guidelines.[33]
22
23

24
25
26 11 Fourth, we chose to utilise the concept of presenteeism in line with researchers who define
27
28 12 it in terms of decreased on-the-job productivity due to health problems.[26] Such an
29
30 13 understanding does ascribe valence to the phenomenon, i.e., a behaviour contributing to lost
31
32 14 productivity that may carry negative influence on the overall work environment.[68] We are,
33
34 15 however, aware of differing opinions among scholars regarding conceptualisations of
35
36 16 presenteeism. Different definitions have different strengths and weaknesses. According to
37
38 17 Johns,[22] a proper definition should (i) neither ascribe motives nor consequences to
39
40 18 presenteeism, and (ii) avoid conflating cause and effect by perceiving productivity loss itself
41
42 19 as presenteeism. To some extent, we do agree with such objections against a productivity-
43
44 20 based definition. A more open understanding, such as simply "showing up for work even
45
46 21 when one is ill",[22, p. 519] does not ascribe a certain valence to the phenomenon, nor does it
47
48 22 presuppose or exclude any particular consequence. We believe, however, that in a
49
50 23 socioeconomic and organisational perspective, situations in which employees attend work
51
52 24 while ill become of interest primarily when performance decrements are in fact involved. In
53
54 25 order to avoid conflating cause and effect, we operationalised alcohol-related presenteeism as
55
56
57
58
59
60

1 the product of a relationship between two measurable variables, i.e., alcohol consumption
2 (predictor/exposure) and work performance (outcome).

CONCLUSIONS

5 Alcohol-related presenteeism (impaired work performance associated with alcohol
6 consumption) stands out as an important but under-researched topic in the research literature.
7 According to this review, evidence does provide some support for the notion that employee
8 alcohol consumption may be associated with impaired work performance. However, due to
9 low research quality and lack of longitudinal designs, existing evidence should still be
10 characterised as inconclusive regarding the prevalence, nature and impact of alcohol-related
11 presenteeism in the workforce. More robust and less heterogeneous research is warranted.

DECLARATIONS

Contributors

15 RWA is the principal investigator and project manager of the WIRUS project. This review
16 study was designed by MMT and RWA. MMT analysed the data and drafted the manuscript.
17 Data selection was performed by MMT, NH and RWA; data extraction by MMT and TB; and
18 quality assessment by MMT and IK. TB, NH, IK WVM and RWA provided scientific input to
19 the different drafts and provided data interpretation. All authors made critical revisions and
20 provided intellectual content to the manuscript, approved the final version to be published,
21 and agreed to be accountable for all aspects of this work.

Funding

1 FIGURE TITLE/LEGEND

2 *Figure 1.* PRISMA flow chart of the study selection process

For peer review only

Supplementary File 1. Results of quality assessment of included associations (n = 132)

Panel A displays quality assessments separately on two key domains; Panel B displays overall assessments according to the "worst score counts algorithm"

Supplementary File 2. Overview of tested associations (n = 132) in the included studies (n = 26)

Association ID	Study (author, year, reference)	Effect size ^a	Significance	Sample size	Adjustment	Classification in review ^b

PRISMA 2009 Checklist

Section/topic	#	Checklist item	Reported on page #
TITLE			
Title	1	Identify the report as a systematic review, meta-analysis, or both.	1
ABSTRACT			
Structured summary	2	Provide a structured summary including, as applicable: background; objectives; data sources; study eligibility criteria, participants, and interventions; study appraisal and synthesis methods; results; limitations; conclusions and implications of key findings; systematic review registration number.	2
INTRODUCTION			
Rationale	3	Describe the rationale for the review in the context of what is already known.	7
Objectives	4	Provide an explicit statement of questions being addressed with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	7
METHODS			
Protocol and registration	5	Indicate if a review protocol exists, if and where it can be accessed (e.g., Web address), and, if available, provide registration information including registration number.	8
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale.	8
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	9
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	9
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	9-10
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	10
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	10
Risk of bias in individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	10-11
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means).	n/a ¹
Synthesis of results	14	Describe the methods of handling data and combining results of studies, if done, including measures of consistency (e.g., I ²) for each meta-analysis.	11

PRISMA 2009 Checklist

Section/topic	#	Checklist item	Reported on page #
Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	n/a ¹
Additional analyses	16	Describe methods of additional analyses (e.g., sensitivity or subgroup analyses, meta-regression), if done, indicating which were pre-specified.	n/a ¹
RESULTS			
Study selection	17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram.	12-13, Fig.1
Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	Table1
Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment (see item 12).	20, SF1 ²
Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: (a) simple summary data for each intervention group (b) effect estimates and confidence intervals, ideally with a forest plot.	20-28, Table2, Table 4, SF2 ³
Synthesis of results	21	Present results of each meta-analysis done, including confidence intervals and measures of consistency.	23, Table3
Risk of bias across studies	22	Present results of any assessment of risk of bias across studies (see Item 15).	n/a ¹
Additional analysis	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	n/a ¹
DISCUSSION			
Summary of evidence	24	Summarize the main findings including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy makers).	28-31
Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review-level (e.g., incomplete retrieval of identified research, reporting bias).	32-34
Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	31-32
FUNDING			
Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review.	34-35

ABSTRACT

Objectives The aim of this review was to explore the notion of alcohol-related presenteeism, i.e., whether evidence in the research literature supports an association between employee alcohol consumption and impaired work performance.

Design Systematic review of observational studies.

Data sources Medline, Web of Science, PsycINFO, Cinahl, Amed, Embase and Swemed+ were searched through October 2018. Reference lists in included studies were hand searched for potential relevant studies.

Eligibility criteria We included observational studies, published 1990 or later as full text empirical articles in peer-reviewed journals in English or a Scandinavian language, containing one or more statistical tests regarding a relationship between a measure of alcohol consumption and a measure of work performance.

Data extraction and synthesis Two independent reviewers extracted data. Tested associations between alcohol consumption and work performance within the included studies were quality assessed, and analysed with frequency tables, cross tabulations and chi square tests of independence.

Results Twenty-six studies were included, containing 132 tested associations. The vast majority of associations (77 %) indicated that higher levels of alcohol consumption were associated with higher levels of impaired work performance, and these positive associations were considerably more likely than negative associations to be statistically significant (OR = 14.00, $phi = .37$, $p < .001$). Alcohol exposure measured by hangover episodes and composite instruments were overrepresented among significant positive associations of moderate and high quality (15 of 17 associations). Overall, 61 % of the associations were characterised by low quality.

1
2
3 1 **Conclusions** Evidence does provide some support for the notion of alcohol-related
4
5 2 presenteeism. However, due to low research quality and lack of longitudinal designs, evidence
6
7 3 should be characterised as somewhat inconclusive. More robust and less heterogeneous
8
9 4 research is warranted. This review, however, does provide support for targeting alcohol
10
11 5 consumption within the frame of workplace interventions aimed at improving employee
12
13 6 health and productivity.

24
25
26
27
28

29 12 **Strengths and limitations of this study**

- 30
31 13 • This systematic review is, to the best of our knowledge, the first to exclusively explore
32
33 14 evidence for the notion of alcohol-related presenteeism.
34
35 15 • The review was based on comprehensive searches in seven scientific databases as well
36
37 16 as in reference lists, and included studies containing data from more than 92 000
38
39 17 employees across 15 countries
40
41
42 18 • As a result of included studies often being characterised by exploring broader aims
43
44 19 related to health and productivity, and by testing several relevant associations between
45
46 20 alcohol consumption and work performance, associations were chosen as the unit of
47
48 21 analysis.
49
50
51 22 • Due to the heterogeneous nature of the included data, meta-analyses were deemed
52
53 23 inappropriate, in particular since measures of alcohol consumption were difficult to
54
55 24 compare across studies/associations (e.g., abstainer vs. drinker; frequency; volume;
56
57 25 hangovers; binge drinking; composite instruments and dependence/abuse diagnoses).
58
59
60

- 1
2
3 • Included data were quality assessed on an association level by means of a
4 parsimonious and conservative assessment system developed specifically for this
5 review.

12 INTRODUCTION

14 Alcohol consumption

17 Excessive alcohol consumption is a major risk factor for disease, disability and mortality,
18 and has been identified as a causal agent in more than 200 disease and injury conditions.¹
19 Higher alcohol consumption has been found to be associated with lowered life expectancy,²
20 and, according to the World Health Organization,³ harmful alcohol consumption is related to
21 approximately three million annual deaths globally. Among the population aged 15 to 49
22 years, alcohol has been identified as the leading risk factor for death and disability-adjusted
23 life-years.⁴ Alcohol is by far the most used and misused psychoactive substance in the
24 workforce,⁵ and one to three out of ten employees can be characterised as risky drinkers in
25 need for interventions,⁶⁻⁹ that is, having a consumption pattern that increases the risk for
26 social-, legal-, medical-, occupational-, domestic- and economic problems.¹⁰ Even though
27 adverse consequences of alcohol tend to accumulate in concordance with increased
28 consumption,^{2,4} it is far from straightforward to establish an appropriate threshold
29 distinguishing between no/low-risk and risky drinking. Whether a particular drinking pattern
30 or consumption level can be conceived of as risky, depends on several factors, such as: (i)
31 effects of alcohol consumption interact with other individual characteristics, such as general
32 health, sociodemographic, physiological and other lifestyle factors,¹¹ and (ii) any level of
33 drinking may be risky given certain circumstances, such as when being pregnant, operating
34 heavy machinery and taking medications known to interact with alcohol.¹² International
35 drinking guidelines, often expressed in terms of a number of alcohol units during a specific

59
60

1
2
3 1 time frame, vary considerably across countries and, moreover, even standard drink sizes vary
4
5 2 internationally.¹² In both research and clinical practice, thresholds for risky drinking are often
6
7 3 applied based on scores on composite instruments, assuming a more complex relationship
8
9 4 between alcohol and health, such as a score of 8 or higher on the Alcohol Use Disorders
10
11
12 5 Identification Test (AUDIT).^{10, 13}

14 6 Alcohol can affect mood as well as cognitive and psychomotor performance.
15
16 7 Psychopharmacological and experimental workplace simulation studies have explored effects
17
18 8 of alcohol intoxication on performance, generally suggesting little consistent impairment at
19
20 9 low to moderate intoxication levels (blood alcohol content (BAC) 0.01 % - 0.08 %), while at
21
22 10 higher BAC levels (≥ 0.09 %) impairment seems to increase quite linearly with task
23
24 11 complexity.¹⁴⁻¹⁷ For comparison, one standard UK drink approximates a BAC of 0.02 % for a
25
26 12 male (age: 40, body weight: 80 kg) or 0.04 % for a female (age: 40, body weight: 60 kg).¹⁸
27
28 13 For both, a BAC of ≥ 0.09 % would be surpassed after three drinks. In a six-hour time
29
30 14 window, a BAC of ≥ 0.09 % would be present after nine (male) or six (female) drinks.
31
32 15 Hangover episodes, defined as an adverse mental and physical state experienced after heavy
33
34 16 drinking when the BAC level returns to zero,^{5(p85)} include symptoms that may be related to
35
36 17 performance decrements, such as headache, nausea, drowsiness, and sensitivity to
37
38 18 light/sound.^{15, 19, 20}

39
40 19 Alcohol consumption may influence activity performance in a variety of domains,
41
42 20 including the occupational sphere. Regarding employees' alcohol consumption, one may
43
44 21 distinguish between workforce overall alcohol consumption (consumption regardless of
45
46 22 context) and work-related alcohol consumption (consumption prior to or during the workday,
47
48 23 as well as in contexts directly related to the work environment or the employment
49
50 24 relationship).^{5, 21-23} According to Frone's integrative conceptual model of employee substance
51
52 25 use and productivity, not showing up at work (absenteeism) and arriving late at work
53
54
55
56
57
58
59
60

1 (tardiness) are primarily believed to be affected by off-the-job drinking, while leaving work
2 early and reduced work performance are thought mainly to be due to on-the-job drinking, that
3 is, drinking within two hours before work, during breaks, or while performing the job.^{5, 24}
4 However, the model does allow for possible cross-over effects between contexts. Off-the-job
5 drinking "may indirectly affect performance outcomes to the extent that it causes off-the-job
6 substance impairment, which when carried into the workplace becomes workplace
7 impairment".^{5(p134)} An association between employees' alcohol consumption and absenteeism
8 is quite well established in the literature, e.g.,²⁵, while alcohol-related presenteeism stands out
9 as a far more under-researched topic.

10

11 **Presenteeism**

12 Presenteeism has been defined in a variety of ways and the concept somewhat suffers
13 from a "definitional creep".^{26(p521)} Two distinct traditions in presenteeism research have been
14 identified.^{26, 27} The first tradition has primarily emphasised the exploration of presenteeism
15 determinants and studied presenteeism as a chosen behaviour or personal choice. In this
16 perspective, presenteeism is defined as the act of "showing up for work even when one is
17 ill",^{26(p519)} or "the phenomenon of people who, despite complaints and ill health that should
18 prompt rest and absence from work, are still turning up at their jobs".^{28(p503)} Hence,
19 presenteeism may be conceived as an alternative to absenteeism and, as such, even as a
20 health-promoting measure within a return to work framework.²⁹ The second tradition has been
21 more oriented towards consequences of this behaviour, in particular related to productivity
22 loss. Researchers in this tradition have defined presenteeism as "decreased on-the-job
23 performance due to the presence of health problems",^{30(p548)} "the health-related productivity
24 loss while at paid work",^{31(p351)} or "the measurable extent to which health symptoms,
25 conditions and diseases adversely affect the work productivity of individuals who choose to

1
2
3 1 remain at work".^{32(p2)} Evidently, the first tradition treats presenteeism as a behaviour,
4
5 2 regardless of its consequences, while the second tradition claims that adverse performance
6
7 3 outcomes are inherent in the conceptualisation of presenteeism.
8
9

10 4 It is plausible to conceive that a variety of health conditions do not result in
11
12 5 productivity impairment and, from an organisational perspective, it may be argued that
13
14 6 situations in which employees attend work while sick become of interest primarily when
15
16 7 performance decrements are involved. In this systematic review, we consider presenteeism as
17
18 8 reduced on-the-job performance due to health problems.³⁰ As such, presenteeism constitutes a
19
20 9 link between on-the-job productivity and employee health,³⁰ addressing the grey area between
21
22 10 optimal work performance and the absence of productivity (i.e., absenteeism).²⁶ Within this
23
24 11 frame, alcohol-related presenteeism can be conceptualised as the presence of a positive
25
26 12 association between alcohol consumption and impaired work performance (or conversely as a
27
28 13 negative association between alcohol consumption and work performance). Alcohol-related
29
30 14 presenteeism is thus operationalised as the product of a relationship between two variables
31
32 15 (exposure: alcohol consumption, outcome: work performance) rather than a single variable
33
34 16 (attending work while sick), rendering it possible to retain the notion of work performance as
35
36 17 inherent in the phenomenon of presenteeism without conflating cause and effect.
37
38
39
40
41

42 18 Performance outcomes at work comprise several phenomena related to productivity.
43
44 19 The concept of presenteeism is most directly associated with task performance. However,
45
46 20 performance may as well be related to contextual performance (such as working extra hours
47
48 21 and helping coworkers), counterproductive behaviour (such as workplace aggression and
49
50 22 property damage) and issues related to job safety, such as injuries resulting from
51
52 23 accidents.^{5(p132)} A recent Norwegian study revealed that employees' alcohol consumption was
53
54 24 a major concern relating to safety issues,³³ and several studies support an association between
55
56 25 alcohol and occupational injuries.³⁴⁻³⁶ However, in the context of the present review, we
57
58
59
60

1
2
3 1 focused on work performance related to task performance, which can be conceived of as most
4
5 2 directly related to on-the-job productivity.
6

7
8 3 Absenteeism and presenteeism have been found to be moderately correlated, and
9
10 4 related by baseline presenteeism being a risk factor for future absenteeism.³⁷ Several authors
11
12 5 have argued that presenteeism may carry more substantial societal costs than absenteeism.
13
14 6 Hemp stated that "the illnesses people take with them to work (...) usually account for a
15
16 7 greater loss in productivity because they are so prevalent, so often go untreated, and typically
17
18 8 occur during peak working years. Those indirect costs have long been largely invisible to
19
20 9 employers".^{38(p2)}
21
22

23
24 10 Known predictors of presenteeism include diseases and disorders (e.g.,
25
26 11 musculoskeletal problems, depression and anxiety), certain individual characteristics (e.g.,
27
28 12 gender, age, job satisfaction, stress and family status), and factors related to the organisational
29
30 13 environment (e.g., employment security, work schedules, workload, managerial support,
31
32 14 corporate culture and leadership style).²⁷ Knowledge of mechanisms underlying presenteeism
33
34 15 is, however, still quite limited. In particular, the impact of individual health risks or
35
36 16 combinations of risks should be researched more extensively.³⁰
37
38
39

40 17

41 42 18 **Rationale and aim**

43
44 19 Some studies have explored alcohol-related presenteeism, either directly or indirectly.
45
46 20 There is, however, a lack of synthesised knowledge, rendering it difficult to assess the
47
48 21 evidence of a possible association between employee alcohol consumption and work
49
50 22 performance. In their review of relationships between psychological, physical and behavioural
51
52 23 health and work performance, Ford et al. found alcohol consumption to be weakly associated
53
54 24 with work performance problems.³⁹ However, this conclusion was based solely on 12 studies
55
56 25 identified in two scientific databases in 2011. It seems imperative to generate new
57
58
59
60

1
2
3 1 accumulated knowledge in order to aid in deciding whether and how workplace interventions
4
5 2 and Workplace Health Promotion Programs (WHPP) should include an emphasis on alcohol
6
7 3 consumption.
8
9

10 4 The aim of this review was to explore whether evidence in the research literature supports
11
12 5 the notion of alcohol-related presenteeism, i.e., whether evidence supports an association
13
14 6 between employee alcohol consumption (overall, as well as work-related) and impaired work
15
16 7 performance.
17
18
19 8

9 **METHODS**

10 **Protocol and registration**

11 This review is registered in the International prospective register of systematic reviews
12 (PROSPERO, ID: CRD42017059620), and is part of the Norwegian national WIRUS project
13 (Workplace Interventions preventing Risky Use of alcohol and Sick leave). Original research
14 from the WIRUS project is published elsewhere.^{9, 23, 40}
15
16

16 **Eligibility criteria**

17 Studies exploring alcohol-related presenteeism, i.e., the relationship between alcohol
18 consumption (exposure) and work performance (outcome) among employees (population)
19 were included in this review. Included studies had to satisfy the following criteria: (i) *type of*
20 *study* (observational study, e.g., case-control, prospective cohort or cross-sectional study); (ii)
21 *type of participants* (the study reported results from a sample of employees, defined as all
22 salaried persons between 16 and 70 years of age, both workers and managers, regardless of
23 employment sector or branch); (iii) *type of measures/tests* (the study reported one or more
24 statistical test(s) of a relationship between a measure of alcohol consumption and a measure
25 of work performance); (iv) *type of publication and language* (the study was reported as a full

59
60

1 text empirical research article published in English or a Scandinavian language in a peer-
2 reviewed scientific journal); and (v) *time* (the study was published year 1990 or later).

3 Studies were excluded if they (i) reported results from samples in which employees
4 were mixed with other groups (e.g., full-time students, unemployed), unless results were
5 reported independently for each group, and/or (ii) reported tests where alcohol and/or work
6 performance were analysed in combination with other factors (e.g., if on-the-job performance
7 was analysed in combination with absenteeism within a wider productivity variable). Time
8 restrictions were set a priori due to drinking behaviour, in particular, resulting from complex
9 and interacting antecedents that are susceptible to changes over time.^{24, 41, 42} Hence, very old
10 studies may suffer from low external validity.

11 12 **Literature search**

13 A primary database search strategy (based on a Medline structure, see Supplementary
14 File 1) was developed and applied in seven scientific databases (Medline; Web of Science;
15 PsycINFO; Cinahl; Amed; Embase; Swemed+). Where necessary, the search strategy was
16 adapted to each database. The primary (Medline) strategy comprised a total of 31 steps, of
17 which 20 were abstract-level text searches, 7 were based on MeSH terms (Medical Subject
18 Headings, Topics, or similar terms), and the remaining were combinations of results applying
19 Boolean operators (OR; AND). First, studies relating to the population (employees) were
20 searched for (employee*; employed; worker*; workforce; work [MeSH]; employment
21 [MeSH]), followed by studies relating to the exposure (alcohol consumption) (alcohol*;
22 drink*; drunk*; hangover; "hang over"; alcohol drinking [MeSH]; binge drinking [MeSH];
23 drinking behavior [MeSH]), and the outcome (work performance) (presenteeism; "job
24 productiv*"; "work productiv*"; "job capacity"; "work capacity"; "job ability"; "work
25 ability"; "job impair*"; "work impair*"; "job performance"; "work performance";

1
2
3 1 presenteeism [MeSH]; work performance [MeSH]). Finally, search blocks for population,
4
5 2 exposure and outcome were combined. Database search results were transferred to EndNote.
6

7
8 3 No restrictions were imposed at the search stage. The primary search strategy was
9
10 4 pilot tested by three reviewers prior to conducting the main searches. Databases were initially
11
12 5 searched in September 2017. An updated search was conducted in October 2018.
13
14 6 Additionally, reference lists in included studies were hand searched for potential relevant
15
16 7 studies.
17
18

19 8 20 21 9 **Study and data selection**

22
23
24 10 After searching the seven databases, hand searching in reference lists in included
25
26 11 studies and removing duplicates, identified studies were screened for relevance on a
27
28 12 title/abstract level. Study selection was based on the results of combining the three main
29
30 13 search blocks in the database search strategy (population, exposure and outcome). For quality
31
32 14 assurance of the search strategy and eligibility criteria, the first 20 studies were independently
33
34 15 screened by three reviewers. The remaining studies were independently screened by two
35
36 16 reviewers. Initial disagreements on eligibility were resolved through discussion. The
37
38 17 reviewers reached consensus. Hence, it was not necessary to consult with a third reviewer.
39
40 18 Potentially relevant studies were independently assessed in full text format for eligibility by
41
42 19 two reviewers. Initial disagreements were resolved through discussion, without the need for
43
44 20 consulting a third reviewer.
45
46
47
48

49 21 50 51 22 **Data extraction**

52
53
54 23 Data from the included studies were extracted independently by two reviewers.
55
56 24 Disagreements were resolved through discussion, without the need to consult a third reviewer.
57
58
59
60

1 We were unable to locate standardised extraction forms appropriate for this review.

2 Therefore, we developed and applied two extraction forms.

3 First, on a study characteristics extraction form, the following pieces of information were
4 extracted from each included article: title, author(s), year of publication, characteristics of
5 study sample, study setting, number of participants included in the study (study sample size),
6 gender and age distribution, study design, data collection method(s), information on the
7 measures of exposure and outcome, and the number of tested associations relevant to the
8 review research question. Second, on an association characteristics extraction form, the
9 following pieces of information were extracted about each relevant association: type of
10 statistical test, number of participants included in association (association sample size), effect
11 size, p-value and/or confidence interval, and information on the measures of exposure and
12 outcome. Extracted data were entered in spreadsheets for further analysis.

14 **Quality assessment**

15 Searches indicated that studies fulfilling the inclusion criteria were characterised by
16 different designs, and by containing several statistical associations between alcohol
17 consumption and presenteeism. Included studies were characterised by exploring broader
18 aims related to health and productivity, while this review emphasises the relationship between
19 alcohol and work performance in particular. Hence, it was deemed inappropriate to conduct
20 overall quality assessment of each study. Instead, relevant tested associations in the included
21 studies were assessed on two key domains: (i) sample size (low quality = <500; moderate
22 quality = 500-999; high quality = ≥ 1000), and (ii) risk of confounding (level of adjustment,
23 the extent to which associations between exposure and outcome were controlled for possible
24 confounding variables: low quality = unadjusted or unclear; moderate quality = adjusted for
25 individual *or* work-related/environmental factor(s); high quality = adjusted for individual *and*

1
2
3 1 work-related/environmental factors). The sample size thresholds were based on the
4
5 2 assumption that alcohol-related presenteeism is a relatively low-prevalent phenomenon in the
6
7 3 workforce. The study of rare events requires greater statistical strength than the study of
8
9 4 frequent events.⁴³ Samples consisting of less than 500 observations were defined as small.
10
11 5 Sample size categorisations were similar to thresholds applied in a recent association-based
12
13 6 review of alcohol-related absenteeism.²⁵ Each association was ascribed an overall quality
14
15 7 judgement (low, moderate or high) based on the assessment of the two key domains,
16
17 8 according to the "worst score counts" algorithm recommended by the COSMIN guidelines.⁴⁴
18
19 9 Hence, an association's overall score was equal to its lowest domain assessment. High-quality
20
21 10 associations were thus characterised by being based on at least 1000 observations and being
22
23 11 adjusted for individual (e.g., gender; age; personality; disease conditions; drug use) as well as
24
25 12 work-related/environmental factors (e.g., work position; work schedule; job characteristics).

30
31 13 The quality assessment procedure was pilot tested on a random sample of 10
32
33 14 associations. Quality assessments were performed independently by two reviewers.
34
35 15 Consensus was reached and initial disagreements were resolved through discussion, without
36
37 16 the need for consulting a third reviewer.
38
39
40
41
42

43 18 **Analysis**

44
45
46 19 Measures of exposure (alcohol consumption) as well as measures of outcome (work
47
48 20 performance) displayed considerable heterogeneity between the included studies. As a result
49
50 21 of the heterogeneous nature of the included data, meta-analyses were deemed inappropriate.
51
52 22 Included data (associations) were instead analysed with frequency tables and cross
53
54 23 tabulations. First, associations were sorted into a frequency table by quality level and overall
55
56 24 association characteristics. Next, four contingency tables were constructed in order to explore
57
58 25 properties of the identified associations more thoroughly: (i) direction and significance, (ii)

1 quality and direction, (iii) publication year and quality, and (iv) significance and quality. The
2 four 2x2 tables were analysed by means of odds ratios (with 95 % confidence intervals) and
3 chi square tests of independence (with phi coefficients). Finally, measurements of alcohol
4 consumption and work performance applied in the included studies were categorised into
5 subgroups.

6 7 **Patient and public involvement**

8 No patients or public were involved in this review study.

9 10 **RESULTS**

11 **Overview of the evidence**

12 Searches in the seven databases resulted in 540 articles (Medline: n = 135; Web of
13 Science: n = 128; PsycINFO: n = 63; Cinahl: n = 22; Amed: n = 3; Embase: n = 189;
14 Swemed+: n = 0). Hand searching in reference lists resulted in an additional nine articles.
15 After duplicate removal (n = 282), a total of 267 unique articles remained. Application of the
16 eligibility criteria resulted in exclusion of 158 studies, leaving 109 potentially relevant
17 articles.

18 Eighty-three studies were excluded after being subjected to full text assessment. The
19 vast majority of these were excluded as a result of not reporting a statistical test of an
20 association between alcohol consumption and work performance (n = 52), or because of
21 publication type (n = 24). Articles not reporting tests of associations were typically
22 characterised by (i) not studying variables that conceptually could be defined as alcohol
23 consumption and/or work performance, and (ii) analysing alcohol consumption and/or work
24 performance in combination with other factors, rendering it impossible to isolate the

1
2
3 1 association of interest. Alcohol being analysed in combination with smoking/other lifestyle
4
5 2 factors, and work performance being analysed in combination with absenteeism constitute
6
7 3 typical examples. Articles excluded on the basis of publication type were typically conference
8
9 4 papers. The study selection process resulted in 26 studies satisfying all inclusion criteria, and
10
11 5 is presented in Figure 1.

22

23
24 10 The 26 included studies were based on data from 92 730 employees from a total of 15
25
26 11 countries (Australia, China, Czech republic, Denmark, Finland, Greece, Ireland, Japan, the
27
28 12 Netherlands, Norway, Portugal, Slovenia, Sweden, Switzerland and the USA). Employees in
29
30 13 the USA constituted the samples in half of the studies (13 of 26). The vast majority of studies
31
32 14 (21 of 26) were based on cross-sectional research designs. A total of 132 associations between
33
34 15 alcohol consumption and work performance were tested in the 26 included studies.
35
36 16 Characteristics of the included studies are presented in Table 1. Characteristics of the included
37
38 17 associations are presented in Supplementary File 2.

For peer review only

1 **Quality of the included data**

2 Ninety-three of the 132 associations (71 %) were based on samples smaller than 1000
3 employees. Approximately half of the associations were unadjusted (n = 63; 48 %), while 29
4 associations (22 %) were adjusted for individual factors as well as for work-
5 related/environmental factors. By applying the "worst score counts" algorithm, 80
6 associations (61 %) were judged as being of low quality, 38 associations (29 %) were of
7 moderate quality, while 14 associations (11 %) were characterised by high quality. Results
8 from quality assessment of the included associations are presented in Supplementary File 3.

10 **Direction, significance, quality and time**

11 One-hundred-two of the 132 tested associations (77 %) indicated a positive
12 relationship between alcohol consumption and work performance, i.e., implying that higher
13 levels of consumption were associated with higher levels of performance impairment.
14 Approximately half of these (n = 56, 55 %) were statistically significant. The majority of
15 positive associations was judged to be of low quality (n = 70, 69 %), followed by moderate (n
16 = 23, 22 %) and high quality (n = 9, 9 %). For instance, in a sample of employees in the USA,
17 Kirkham *et al.*⁵¹ found that risky drinking, as measured with the CAGE questionnaire,⁶⁹ was
18 associated with impaired work performance, measured with the Work Limitations
19 Questionnaire,⁷⁰ both overall (ID36, $\beta = .20, p < .001$) as well as among those aged <45 (ID37,
20 $\beta = .22, p < .001$) and ≥ 45 (ID38, $\beta = .20, p < .001$). Among Finnish employees, Pensola *et*
21 *al.*⁵³ found that high hangover frequency (at least six hangovers during the past 12 months),
22 compared to low frequency (no alcohol or less than six hangovers during the past 12 months),
23 was associated with moderate or poor self-reported work ability (ID41, PRR = 1.15, 95% CI:
24 1.0, 1.3). In a study of Norwegian employees, Aas *et al.*⁴⁰ found that higher binge drinking
25 frequency (measured with a single item from the AUDIT)^{10, 13} was positively related to the

1 experienced degree of impaired work performance (measured with a single item from the
2 Work Productivity and Activity Impairment questionnaire)⁷¹ during the past seven days
3 (ID127, $\beta = .06, p < .01$).

4 Twenty-five of the 132 tested associations (19 %) indicated a negative relationship,
5 i.e., implying that higher levels of alcohol consumption were associated with lower
6 performance impairment (higher work performance). Only two of these associations were
7 statistically significant, and both of these were of low quality. These two associations (ID66, r
8 $= .10, p < .01$, and ID68, $r = .09, p < .01$, in Friedman *et al.*⁶⁰) tested the relationship between
9 duration of alcohol use and overall work performance, and found that longer duration, as
10 opposed to shorter duration, was associated with higher work performance.

11 Five associations (4 %) were not possible to classify as either positive or negative.
12 They were characterised by (i) finding no differences in work performance between compared
13 alcohol consumption groups (ID102, $M_{\text{diff}} = 0.0, p = .68$, in Moore *et al.*⁶⁶; ID130, OR = 1.00,
14 $p = \text{ns}$, in van den Berg *et al.*⁶⁸); (ii) by finding significant differences between multiple
15 consumption groups, but without a consistent positive/negative pattern (ID28, unclear effect
16 size, $p < .001$), and ID29, unclear effect size, $p = .03$, in Kim *et al.*⁵⁰); or (iii) by finding a J-
17 shaped pattern where abstainers scored comparable to moderate-level drinkers on impaired
18 performance (i.e., higher than low-level drinkers), but still lower than heavy drinkers (ID98,
19 unclear effect size, $p < .05$, in Moore *et al.*⁶⁶). The identified associations, sorted by quality
20 level and overall association characteristics, are presented in Table 2.

Table 2

Identified associations (n = 132) according to direction/significance and assessed quality level

Quality level	Direction and significance of associations				
	Significant positive ^a association	Significant negative ^b association	Non-significant positive association	Non-significant negative association	Other ^c
Low	[1],[2],[3],[4],[5],[10],[12],[17],[19],[26],[39],[49],[51],[54],[55],[56],[58],[59],[60],[62],[64],[67],[69],[77],[78],[81],[82],[83],[84],[95],[96],[97],[118],[119],[120],[121],[124],[125]	[66],[68]	[6],[7],[8],[9],[11],[13],[14],[16],[18],[20],[21],[23],[25],[27],[48],[50],[53],[57],[61],[63],[65],[73],[74],[75],[76],[79],[80],[104],[107],[122],[131],[132]	[15],[22],[24],[92],[93],[94]	[28],[130]
Moderate	[40],[42],[43],[44],[46],[47],[52],[101],[106],[109],[110],[115],[123]		[34],[35],[45],[91],[100],[103],[105],[117],[128],[129]	[30],[31],[32],[33],[90],[99],[108],[111],[112],[113],[114],[116]	[29],[98],[102]
High	[36],[37],[38],[41],[127]		[70],[71],[72],[126]	[85],[86],[87],[88],[89]	

Note. Number in brackets = association ID; ^a Higher level of alcohol associated with higher level of presenteeism; ^b Lower level of alcohol associated with higher level of presenteeism, or higher level of alcohol associated with lower level of presenteeism; ^c Inconsistent direction, no relationship or J-shaped relationship between alcohol and presenteeism

1
2
3 1 Positive associations were considerably more likely than negative associations to be
4
5 2 statistically significant (OR = 14.00, 95 % CI: 3.1 – 65.5; χ^2 (1, n = 127) = 17.80, p = .000, ϕ
6
7 = .37). On the other hand, negative associations were less likely than positive associations to
8
9 3 be of low quality (OR = 0.22, 95 % CI: 0.1 – 0.6; χ^2 (1, n = 127) = 11.37, p = .001, ϕ = -.30).
10
11 4 Furthermore, recent studies (\geq year 2000) were more likely than older studies ($<$ year 2000) to
12
13 5 be of moderate or high quality (OR = 2.95, 95 % CI: 1.30 – 6.79; χ^2 (1, n = 132) = 6.96, p
14
15 6 = .008, ϕ = .23). There was no significant relationship between whether associations were
16
17 7 significant and whether they were of moderate/high or low quality. The four 2x2 contingency
18
19 8 tables are presented in Table 3.

Table 3

Cross tabulations of included associations according to direction, significance, quality and publication year

Direction			Direction		
Significance	Positive % (n)	Negative % (n)	Quality	Positive % (n)	Negative % (n)
Significant	54.9 (56)	8.0 (2)	Moderate/high	31.4 (32)	68.0 (17)
Non-significant	45.1 (46)	92.0 (23)	Low	68.6 (70)	32.0 (8)
OR= 14.00*** (3.130 – 65.53)			OR = 0.22** (0.08 – 0.55)		
$\chi^2 (1, n = 127) = 17.80, p = .000, phi = .37$			$\chi^2 (1, n = 127) = 11.37, p = .001, phi = -.30$		
Publication year			Significance		
Quality	\geq year 2000 % (n)	< year 2000 % (n)	Quality	Significant % (n)	Non-sign. % (n)
Moderate/high	47.2 (42)	23.3 (10)	Moderate/high	32.8 (20)	44.9 (31)
Low	52.8 (47)	76.7 (33)	Low	67.2 (41)	55.1 (38)
OR= 2.95** (1.30 – 6.70)			OR= 0.60 ^{ns} (0.29 – 1.22)		
$\chi^2 (1, n = 132) = 6.96, p = .008, phi = .23$			$\chi^2 (1, n = 130) = 2.00, p = .157^{ns}, phi = -.12$		

OR = odds ratio, with 95% confidence interval; χ^2 = chi square test of independence, with phi coefficient; ** $p < .01$; *** $p < .001$; ns = non-significant

1 **Measurements of alcohol consumption and work performance**

2 Categorisation of the applied measurements of alcohol consumption in the 26 included
3 studies revealed eight subgroups: (i) consumption status (e.g., current alcohol drinker
4 (yes/no), applied in Yu *et al.*⁵⁹); (ii) drinking frequency (e.g., number of times drunk during
5 past three months, applied in Ames *et al.*²¹; typical frequency of alcohol consumption during
6 past year, applied in Aas *et al.*⁴⁰); (iii) drinking intensity (e.g., average number of alcohol
7 drinks during the past week, applied in Adler *et al.*⁴⁵); (iv) drinking volume (e.g., monthly
8 frequency x typical quantity during past 30 days, applied in Blum *et al.*⁶²); (v) binge drinking
9 (e.g., binge drinking (6 or more drinks on a single occasion) frequency during past year,
10 applied in Aas *et al.*⁴⁰); (vi) hangover (e.g., frequency of hangover episodes at work during
11 past year, applied in Ames *et al.*²¹); (vii) composite instruments comprising several aspects of
12 consumption, such as frequency, intensity and alcohol problems (e.g., the AUDIT,^{10, 13}
13 applied in Richmond *et al.*⁵⁴); and (viii) alcohol-related diagnosis (e.g., DSM-IV diagnosis of
14 alcohol abuse, applied in Lim *et al.*⁶⁴).

15 The 26 included studies contained a total of six work performance measurement
16 categories: (i) overall work performance/impairment (e.g., supervisor ratings of overall work
17 performance, applied in Lowmaster *et al.*⁶⁵; self-reported current work performance compared
18 to lifetime best, applied in Furu *et al.*⁶⁷; Work Limitations Questionnaire sum score,⁷⁰ applied
19 in Kirkham *et al.*⁵¹); (ii) domain-specific work performance/impairment (e.g., Work
20 Limitations Questionnaire subscale Time management,⁷⁰ applied in Adler *et al.*⁴⁵); (iii)
21 impaired performance quantity (e.g., number of days working below a normal level of
22 performance during past 12 months, applied in Fisher *et al.*⁴⁷; estimated percent impaired
23 performance during past week, applied in Boles *et al.*⁶¹); (iv) impaired performance frequency
24 (e.g., frequency of impaired performance episodes during past 12 months, applied in Schou *et*
25 *al.*⁵⁵); (v) prognosis of work performance (e.g., self-assessed probability of good work

- 1
2
3 1 performance within frame of 6 months, applied in Karlsson *et al.*⁴⁸); and (vi) work
4
5 2 performance status (e.g., impaired work performance during past 4 weeks (yes/no), applied in
6
7 3 Yu *et al.*⁵⁹). The identified associations, sorted according to measurements of alcohol
8
9 4 consumption and work performance, are presented in Table 4.

1
2
3 1 In the 132 included associations, the most frequently applied alcohol measurement was
4
5 2 drinking intensity (n = 28, 21 %) and composite instruments (n = 27, 20 %). Overall work
6
7 3 performance/impairment (n = 67, 51 %) and quantity of impaired performance (n = 35, 27 %)
8
9 4 were the most frequently utilised work performance measures. When exploring the group of
10
11 5 associations characterised by being significant positive and of moderate or high quality (n =
12
13 6 18), the vast majority of these (n = 15) applied either hangover (n = 9) or composite
14
15 7 instruments (n = 6) as alcohol consumption measures.

9 **DISCUSSION**

23
24 10 The aim of this review was to explore whether evidence in the research literature
25
26 11 supports the notion of alcohol-related presenteeism, i.e., whether evidence supports an
27
28 12 association between employee alcohol consumption and work performance. Twenty-six
29
30 13 studies met the eligibility criteria, containing a total of 132 tested associations between
31
32 14 alcohol consumption and presenteeism, based on data from 92 730 employees in 15 countries.
33
34

35 15 The vast majority of the associations (102 of 132, 77 %) indicated a positive
36
37 16 relationship between alcohol consumption and impaired work performance, implying that
38
39 17 higher levels of alcohol consumption were associated with higher levels of impaired
40
41 18 performance. Furthermore, positive associations were considerably more likely than negative
42
43 19 associations to be statistically significant.
44
45

46
47 20 Alcohol use has the potential for influencing cognitive and psychomotor performance,
48
49 21 which may explain why employees' alcohol consumption is associated with work
50
51 22 performance. In particular, hangover episodes are characterised by symptoms that can induce
52
53 23 work impairments (headache, nausea, drowsiness etc.),^{15, 19, 20} and alcohol intoxication, at
54
55 24 least at higher blood alcohol content, may produce work impairments that increase linearly
56
57 25 with task complexity.¹⁴⁻¹⁷ Positive associations between alcohol consumption and
58
59
60

1 performance impairments are not so surprising in light of knowledge on the relationship
2 between alcohol consumption and absenteeism. In their review, Schou and Moan found that
3 employees' consumption was positively associated with both short-term and long-term sick
4 leave.²⁵ The complementary hypothesis of the relationship between absenteeism and
5 presenteeism claims that these behaviours are both related to employees' overall health status
6 and that they are positively associated.²⁷ Research has demonstrated moderate positive
7 correlations between absenteeism and presenteeism and that presenteeism may be a risk factor
8 for future absenteeism.^{27, 37}

9 Alcohol measurements based on hangovers and composite instruments were
10 overrepresented in associations characterised by being significant positive, and of moderate or
11 high quality. Hangovers tend to result from binge drinking episodes, or drinking shortly
12 before work. Such short-term impairment-producing consumption may be more predictive of
13 work impairments than for instance typical drinking frequency, which instead may be more
14 predictive of long-term ill-health consequences.⁷² Composite instruments, such as the
15 AUDIT,^{10, 13} tend to assume a more complex relationship between alcohol, health and
16 performance than what may be the case for more basic measurements (e.g., drinking
17 frequency or intensity). Hence, a composite instrument measuring both consumption and
18 experienced alcohol problems may be more predictive of productivity outcomes such as work
19 performance.

20 While most alcohol measures in the included studies can be said to capture somewhat
21 different aspects of alcohol consumption (e.g., frequency, intensity, volume, binge episodes
22 and hangovers), four studies did report abuse/dependence diagnoses (diagnosis vs. no
23 diagnosis) as measure of exposure.^{49, 57, 60, 64} One may argue that an alcohol-related diagnosis,
24 focusing on harms and consequences as well as on use, is conceptually different from more
25 direct measures of consumption. These studies are thus difficult to compare with other studies

1 in this review, even though they do not differ considerable in terms of overall conclusions
2 regarding the relationship between exposure and outcome. Moreover, these studies are
3 difficult to interpret in the context of the present review's research question. One may assume
4 that individuals satisfying the criteria for an alcohol-related diagnosis are indeed characterised
5 by having high consumption levels. However, the consumption levels of those not satisfying
6 the diagnostic criteria in these studies remain unknown.

7 The majority of positive associations were judged to be of low quality, and 25 of 132
8 associations (19 %) even indicated a negative relationship, i.e., implying that higher levels of
9 alcohol consumption were associated with lower performance impairments (higher
10 performance). Moreover, five associations were inconsistent, i.e., not possible to classify as
11 positive or negative, or did not reveal any association between alcohol consumption and work
12 performance at all. Negative associations were less likely than positive associations to be of
13 low quality.

14 Only two associations categorised as negative reported statistically significant findings.
15 These associations, both reported in Friedman *et al.*⁶⁰, tested the relationship between
16 duration of alcohol use and overall work performance, and found that longer duration (higher
17 exposure) was associated with lower work impairment. Basically, these results may imply that
18 more experienced drinkers report lower levels of work impairment than less experienced
19 drinkers. As such, rather than implying that higher consumption could be related to lower
20 impairments, they may reflect that experienced drinkers have developed higher tolerance
21 levels and more sophisticated coping strategies than less experienced drinkers.

22 The relationship between alcohol consumption and health outcomes has, in some studies,
23 been described as a J-shaped curve where low to moderate consumption is associated with
24 better health outcomes than non-drinking.⁷³ In their study of manufacturing company
25 employees in the USA, Moore *et al.*⁶⁶ found a J-shaped relationship between alcohol

1
2
3 1 consumption and percentage of time at work spent "goofing off". In this study, abstainers
4
5 2 scored higher on "goof-off time" than low-moderate drinkers, but lower than heavy drinkers.
6
7 3 J-shaped relationships have also been found between alcohol consumption and cognitive
8
9 4 outcomes.⁷⁴ It is, however, somewhat unclear whether low-moderate levels of alcohol
10
11 5 consumption in fact have some protective effects or whether such findings are products of
12
13 6 confounding.^{4, 73, 75} For instance, studies have demonstrated that heavy drinking is associated
14
15 7 with cognitive deficits that endure long after abstinence.⁷⁶ Such deficits, due to former heavy
16
17 8 drinking, may impair work performance, even though the employee is currently categorised as
18
19 9 an abstainer. A recent review found no mortality benefits for low-volume drinking compared
20
21 10 to lifetime abstention or occasional drinking, when adjusting for study design and
22
23 11 characteristics.⁷⁷ Nevertheless, potential curvilinear relationships between alcohol
24
25 12 consumption and health outcomes may contribute to explain why a considerable proportion of
26
27 13 associations failed to demonstrate significant positive relationships. Moreover, on-the-job
28
29 14 performance outcomes may be more directly affected by on-the-job drinking (within two
30
31 15 hours before work, during breaks or while performing the job) than by off-the-job drinking,
32
33 16 even though off-the-job consumption may translate into workplace impairment.⁵ Among the
34
35 17 studies included in this review, only one (Ames *et al.*²¹) contained explicit measures of on-
36
37 18 the-job drinking, while the remaining studies measured overall consumption (consumption
38
39 19 regardless of context). Moreover, overall consumption may have differential impact on
40
41 20 different domains. In a study of employees in Norway, Aas *et al.*⁴⁰ found that overall
42
43 21 consumption demonstrated stronger associations with performance impairments outside the
44
45 22 workplace compared to work performance, which may be due to employees moderating (self-
46
47 23 regulating) their behaviour at work as a result of potential sanctions from employers. Self-
48
49 24 regulatory motivations and mechanisms may contribute to hide alcohol-related presenteeism,
50
51
52
53
54
55
56
57
58
59
60

1
2
3 1 which may complicate the exploration of associations between alcohol consumption and work
4
5 2 performance.
6
7
8 3

4 **Implications**

5 Overall, this review provides support for the notion of alcohol-related presenteeism,
6 i.e., that employee alcohol consumption may be associated with performance decrements at
7 work. Research has, although often demonstrating somewhat mixed results, shown that
8 employees' alcohol consumption is related to occupational outcomes, including absenteeism
9 and occupational injuries.^{25, 34-36} The results of this review on alcohol-related presenteeism
10 imply that impaired work performance may be an additional detrimental occupational
11 outcome related to alcohol consumption. As such, this review provides further support for
12 targeting alcohol consumption within workplace interventions aimed at improving employee
13 health and productivity, rather than implying that interventions should specifically target
14 presenteeism behaviour. Further research is necessary for determining whether and how
15 presenteeism should be targeted directly in interventions.

16 It is not possible to draw firm conclusions regarding the relationship between alcohol
17 consumption and work performance. The majority of identified evidence was of low quality
18 as a result of low power (small sample sizes) and/or risk of confounding. Moreover, the
19 majority of identified studies were cross-sectional, and thereby unable to draw causal
20 inferences about the relationship between exposure and outcome. Above all, this review
21 implies the need for further research. First, future research would benefit from studying
22 alcohol-related presenteeism by means of more robust study designs that better enable
23 exploration of causal mechanisms and development over time. A more thorough exploration
24 of alcohol as a risk factor for impaired work performance could be done by means of
25 retrospective case-control studies, where historical data sources containing information on

1
2
3 1 alcohol consumption (such as medical records) are utilised in order to compare work impaired
4
5 2 (cases) with non-impaired employees (controls). How the relationship between alcohol and
6
7 3 work performance develops over time can be explored with prospective cohort studies, where
8
9 4 researchers can follow and compare risky and non-risky drinkers with repeated measurements
10
11 5 of work performance.
12
13

14 6 Second, both alcohol consumption and work performance are conceptualised and
15
16 7 measured very differently across current studies. Such heterogeneity makes it difficult to
17
18 8 explore findings in the literature by means of meta-analyses. Progress in the field seems to
19
20 9 hinge on researchers' ability to reach more agreement on how to conceptualise these variables
21
22 10 and measure them utilising instruments with satisfactory psychometric properties. This seems
23
24 11 particularly true for the concept of presenteeism. According to an expert panel from the
25
26 12 American College of Occupational and Environmental Medicine,^{31(p351)} productivity
27
28 13 instruments should be supported by scientific evidence, be applicable to the specific work
29
30 14 setting, support decision making, and be practical. Ospina *et al.*⁷⁸ concluded that the
31
32 15 following three instruments were most strongly supported by evidence: The Stanford
33
34 16 Presenteeism Scale (6-item version),⁷⁹ the Endicott Work Productivity Scale (EWPS),⁸⁰ and
35
36 17 the Health and Work Questionnaire (HWQ).⁸¹ Regardless of design, future research would
37
38 18 benefit from measurement triangulation. For instance, alcohol consumption could be
39
40 19 measured with a validated self-report composite measure (e.g., the AUDIT measuring both
41
42 20 consumption and alcohol-related harm, or the abbreviated AUDIT-C measuring only
43
44 21 consumption),^{10, 13} items separating off-the-job and on-the-job drinking and hangovers, and an
45
46 22 alcohol biomarker test (such as the carbohydrate-deficient transferrin (CDT) test). Work
47
48 23 performance could be measured with a validated self-report composite instrument (e.g., the
49
50 24 Stanford Presenteeism Scale),⁷⁹ as well as with supervisors' ratings of employee work
51
52 25 performance and, where possible, register data on task performance. Measurement
53
54
55
56
57
58
59
60

1
2
3 1 triangulation may provide more valid measures as well as enabling exploration of a potential
4
5 2 correspondence between consumption contexts, impairment contexts and performance
6
7
8 3 outcomes.

9
10 4 Third, future research would benefit from taking possible mediators and moderators of
11
12 5 the relationship between alcohol and work performance into account, such as
13
14 6 sociodemographic, general health, work-related, and other lifestyle factors.
15
16
17 7

18 19 8 **Methodological considerations**

20
21 9 This review has some limitations. First and foremost, due to the heterogeneous nature
22
23
24 10 of the identified data, we were unable to perform meta-analyses on the included data.
25

26 11 Second, it may be considered a limitation that this review utilised associations and not
27
28 12 studies as the unit of interest. Associations were deemed the appropriate unit of interest in this
29
30 13 review for two reasons: (i) included studies were characterised by exploring broader aims
31
32 14 related to health and productivity, while this review specifically aimed at exploring the
33
34 15 relationship between alcohol consumption and work performance, and (ii) in several studies,
35
36 16 multiple associations between alcohol consumption and work performance were tested (often
37
38 17 with different measures and subgroups within each study).
39

40
41
42 18 Third, this review did not utilise a previously validated critical appraisal tool (CAT) for
43
44 19 assessment of included primary research. One reason for this is that studies based on different
45
46 20 study designs were included in the review. At present, there exists no generic gold standard
47
48 21 CAT for application across study designs.^{82, 83} A second reason is that the current review
49
50 22 emphasised associations rather than studies as the unit of interest. Hence, it was deemed more
51
52 23 appropriate to develop a parsimonious and conservative quality assessment system in which
53
54 24 each association was evaluated based on power (sample size) and risk of confounding (level
55
56 25 of adjustment). Deliberately, we chose a conservative approach to quality assessment by
57
58
59
60

1 ascribing each association an overall score in accordance with the "worst score counts"
2 algorithm. Such an approach is in line with the COSMIN guidelines.⁴⁴

3 Fourth, articles published before 1990 were not eligible for inclusion in this review. This
4 exclusion criterion was set a priori as a result of old studies having limited external validity
5 due to changes in drinking behaviour over time. Time restrictions were imposed at the study
6 selection phase, not in the literature search phase of the review. This decision was made in
7 order to be able to assess the magnitude of potentially relevant research published prior to
8 1990. Seventeen articles from the 1980s were excluded in the title/abstract screening.
9 However, these articles did not satisfy all the other inclusion criteria and were, thus, not
10 exclusively excluded based on year of publication. Hence, we do not find it very likely that
11 relevant studies published before 1990 have been missed.

12 Fifth, we chose to utilise the concept of presenteeism in line with researchers who define it
13 in terms of decreased on-the-job productivity due to health problems.³⁰ Such an understanding
14 does ascribe valence to the phenomenon, i.e., a behaviour contributing to lost productivity
15 that may carry negative influence on the overall work environment.⁸⁴ We are, however, aware
16 of differing opinions among scholars regarding conceptualisations of presenteeism. Different
17 definitions have different strengths and weaknesses. According to Johns,²⁶ a proper definition
18 should (i) neither ascribe motives nor consequences to presenteeism, and (ii) avoid conflating
19 cause and effect by perceiving productivity loss itself as presenteeism. To some extent, we do
20 agree with such objections against a productivity-based definition. A more open
21 understanding, such as simply "showing up for work even when one is ill",^{26(p519)} does not
22 ascribe a certain valence to the phenomenon, nor does it presuppose or exclude any particular
23 consequence. We believe, however, that in a socioeconomic and organisational perspective,
24 situations in which employees attend work while ill become of interest primarily when
25 performance decrements are in fact involved. In order to avoid conflating cause and effect, we

1 operationalised alcohol-related presenteeism as the product of a relationship between two
2 measurable variables, i.e., alcohol consumption (predictor/exposure) and work performance
3 (outcome).

CONCLUSIONS

4
5 Alcohol-related presenteeism (impaired work performance associated with alcohol
6 consumption) stands out as an important but under-researched topic in the research literature.
7 According to this review, evidence provides support for the notion that employee alcohol
8 consumption may be associated with impaired work performance. However, due to low
9 research quality and lack of longitudinal designs, existing evidence should still be
10 characterised as inconclusive regarding the prevalence, nature and impact of alcohol-related
11 presenteeism in the workforce. More robust and less heterogeneous research is warranted.

DECLARATIONS

Contributors

12
13
14
15
16 RWA is the principal investigator and project manager of the WIRUS project. This
17 review study was designed by MMT and RWA. MMT analysed the data and drafted the
18 manuscript. Data selection was performed by MMT, NH and RWA; data extraction by MMT
19 and TB; and quality assessment by MMT and IK. TB, NH, IK WVM and RWA provided
20 scientific input to the different drafts and provided data interpretation. All authors made
21 critical revisions and provided intellectual content to the manuscript, approved the final
22 version to be published, and agreed to be accountable for all aspects of this work.

Funding

1
2
3 1 The review study is funded by the Norwegian Directorate of Health and the Research
4
5 2 Council of Norway. The funding bodies had no role in the design of the review or in data
6
7 3 analysis or interpretation.

^a r = correlation coefficient; b = unstandardised regression coefficient; RR = relative risk; OR = odds ratio; β = standardised regression coefficient; PRR = prevalence risk ratio; χ^2 = chi square; M_{diff} = mean difference; η^2 = eta squared

^b ↑ = positive association; ↓ = negative association; | = inconsistent direction; * = significant association; ns = non-significant association; L = low quality association; M = moderate quality association; H = high quality association

Supplementary File 3. Results of quality assessments of included associations (n = 132)

Panel A displays quality assessments separately on two key domains (sample size and level of adjustment). Panel B displays overall assessments according to the “worst score counts” algorithm.

MOOSE Checklist for Meta-analyses of Observational Studies

Item No	Recommendation	Reported on Page No
Reporting of background should include		
1	Problem definition	2,9
2	Hypothesis statement	n/a
3	Description of study outcome(s)	6-8
4	Type of exposure or intervention used	4-6
5	Type of study designs used	9
6	Study population	5-6,9
Reporting of search strategy should include		
7	Qualifications of searchers (eg, librarians and investigators)	1,10-11
8	Search strategy, including time period included in the synthesis and key words	10-11, SF1
9	Effort to include all available studies, including contact with authors	11
10	Databases and registries searched	10, SF1
11	Search software used, name and version, including special features used (eg, explosion)	11
12	Use of hand searching (eg, reference lists of obtained articles)	11
13	List of citations located and those excluded, including justification	n/a
14	Method of addressing articles published in languages other than English	9-10
15	Method of handling abstracts and unpublished studies	9-10
16	Description of any contact with authors	n/a
Reporting of methods should include		
17	Description of relevance or appropriateness of studies assembled for assessing the hypothesis to be tested	9-10,11
18	Rationale for the selection and coding of data (eg, sound clinical principles or convenience)	11-12
19	Documentation of how data were classified and coded (eg, multiple raters, blinding and interrater reliability)	11-12
20	Assessment of confounding (eg, comparability of cases and controls in studies where appropriate)	12-13
21	Assessment of study quality, including blinding of quality assessors, stratification or regression on possible predictors of study results	12-13
22	Assessment of heterogeneity	12
23	Description of statistical methods (eg, complete description of fixed or random effects models, justification of whether the chosen models account for predictors of study results, dose-response models, or cumulative meta-analysis) in sufficient detail to be replicated	13-14
24	Provision of appropriate tables and graphics	Fig1, SF1
Reporting of results should include		
25	Graphic summarizing individual study estimates and overall estimate	n/a
26	Table giving descriptive information for each study included	Table1
27	Results of sensitivity testing (eg, subgroup analysis)	n/a
28	Indication of statistical uncertainty of findings	SF2

Item No	Recommendation	Reported on Page No
Reporting of discussion should include		
29	Quantitative assessment of bias (eg, publication bias)	22, SF3
30	Justification for exclusion (eg, exclusion of non-English language citations)	37
31	Assessment of quality of included studies	36
Reporting of conclusions should include		
32	Consideration of alternative explanations for observed results	32-34
33	Generalization of the conclusions (ie, appropriate for the data presented and within the domain of the literature review)	34
34	Guidelines for future research	34-35
35	Disclosure of funding source	38-39
