5	Table S4. Average concentrations of the compounds and parameters identified from Bruker SGF profiling.	S11
6	Figure S1. Signal assignment of a representative ¹ H-NMR spectrum of apple juice (0 – 5.5 ppm).	S12
7	Figure S2. Correlation map generated from the 86 x 96 matrix. The variables are grouped by similarity.	S13
8	Figure S3. (A) LV1/LV2 scores plot of the PLS-DA model developed to discriminate early-season juices (class 1) from late (class 2) harvest cultivars. Most discriminative markers are shown in the regression vector plot (C) and VIP score plot (D). Area Under the Curve (AUC) of Receiver Operating Characteristic (ROC) (E) and sensitivity and specificity (F) plot of the PLS-DA model.	S14

Analytical platforms' reliability

NMR

This study focuses on the employment of a recently developed NMR-based juice screener (SGF profiling) for the analysis of juices obtained by ancient Danish apple cultivars. It is known that two NMR determinations give the same results (large metabolomic studies usually employ single determination); this is why only one measurement was performed in this work. Even though two independent preparations of the juices would have better described the intra-juice variability, our study was more oriented toward describing the inter-apple juice variability rather than describing each apple cultivar in detail.

Ion Chromatography (IC)

To measure IC accuracy, a Quality Control sample was prepared by mixing five standards (citric acid, malic acid, glucose, fructose and sucrose) and it was run seven times. The areas under the peak corresponding to each molecule together with their standard deviation, average and percent coefficient of variation (%CV) across the seven replicates, are reported in the table below. The reported values of %CV (less than 2%) confirm the reliability of the IC platform employed in our study.

	Citric acid	Malic acid	Glucose	Fructose	Sucrose
Standard mix_1	10.619	41.143	7028.728	11763.45	3505.707
Standard mix_2	10.484	41.032	6976.936	11575.77	3493.564
Standard mix_3	10.669	41.35	7028.266	11603.51	3578.934
Standard mix_4	10.544	41.296	7017.829	11575.37	3598.164
Standard mix_5	10.284	40.249	6759.458	11312.84	3451.197
Standard mix_6	10.362	40.278	6767.272	11318.27	3454.808
Standard mix_7	10.358	40.279	6751.946	11307.38	3439.516
<i>STANDARD DEVIATION</i>	0.1449997	0.5111117	136.6152	180.9388	63.18577
<i>AVERAGE</i>	10.474286	40.803857	6904.348	11493.8	3503.127
<i>CV^a</i>	0.0138434	0.0125261	0.019787	0.015742	0.018037
<i>%CV</i>	1.38	1.25	1.98	1.57	1.80

^aCV = Coefficient of Variation calculated on the 7 replicates.

Gas Chromatography/Mass Spectrometry (GC-MS)

The accuracy of the analysis of aroma compounds by dynamic headspace GC-MS was already tested in our laboratory on a different apple juice dataset consisting of seventeen samples analyzed in quadruplicate. The %CV for each aroma compound, across the four replicates, is reported in table below. For most compounds, the %CV was between 0.2 and 15%. For few compounds the values were higher, mainly due the compounds being present in very small concentrations.

Aroma compound	%CV^a
<i>Alcohols</i>	
2-methyl-1-butanol	0.2
