Supplementary methods

Solutions and buffers

Britton-Robinson (BR) universal buffers[1] (40 mmol L⁻¹, pH 3 - 7) were prepared by mixing aqueous solutions of H₃BO₃ (40 mmol L⁻¹), H₃PO₄ (40 mmol L⁻¹), and H₃CCO₂H (40 mmol L⁻¹) and adjusting the pH to the desired value with aqueous NaOH solution (0.2 mol L⁻¹) at 25 °C.

Molar absorption coefficient (ϵ)

Since the direct weighting of betalains is difficult due to limited amount of substance and high hygroscopicity, the molar absorption coefficient (ϵ) of the pBeets and the mepBeets was determined using an endpoint method[2] (Figure S11). Briefly, the alkaline hydrolysis of betalains in BR buffer (pH 7 or 11, 40 mmol L⁻¹) was spectrophotometrically monitored. The initial pigment concentration and ϵ of all betalains were determined by comparing the absorption of the resulting betalamic acid solution ($\epsilon^{424\text{nm}} = 27,000 \text{ L mol}^{-1} \text{ cm}^{-1}$)[3] with that of betanin solutions of known concentrations. The betalamic acid solutions were stable under the experimental conditions, and no appreciable change in the spectral properties could be detected after 30 min.

Fluorescence quantum yields (Φ_{FL})

Fluorescence quantum yields (Φ_{FL}) were determined using rhodamine B as the secondary fluorescence standard (ethanol solution; $n_{\text{D}} = 1.3616$; $\Phi_{\text{Fl}} = 0.5$)[4]. Fluorescence spectra of the standard and the betalains were taken under identical spectrometer conditions (excitation (EX) at 490 nm, emission (EM) wavelength range: 510 – 800 nm, slits 20 nm (EX and EM), photomultiplier power 600 V, 25 ± 1 °C) on a Varian Eclipse spectrofluorimeter equipped

with a thermostated cell holder. Plots of the integrated fluorescence intensity vs. absorbance were submitted to linear regression analysis and the slopes α_X and α_S were used to calculate the Φ_{FL} using Eq. S1.

$$\Phi_{FL}^X = \Phi_{FL}^S \left(\frac{\alpha_X}{\alpha_S} \right) \left(\frac{n_X}{n_S} \right)^2 \quad (\text{Eq. S1})$$

where n is the refractive index of the solvent and Φ_{FL} are the absolute quantum yields; X refers to the sample and S to the standard.

Cyclic Voltammetry

Measurements were carried out in a Autolab PGSTAT101 potentiostat/galvanostat controlled with NOVA software and equipped with a 10 mL conventional electrochemical cell at room temperature. A glassy carbon working electrode (diameter of electrode disk = 2 mm), a platinum wire auxiliary electrode and a Ag|AgCl (KCl, sat.) reference electrode were used; scan rate: 50 mV s⁻¹, potential range: -1.0 to 1.0 V or -1.0 to 1.25 V; [betalain] = 0.1 mmol L⁻¹ (in BR buffer). Before each experiment, the working electrode was polished with 0.05 μm sized aluminum oxide particles (60 cycles) and washed with water under ultrasound irradiation for 1 min. The number of proton lost/gained by electron ratio (ν/n) was calculated from the Nernst plot (Figure 2); Nernst limit of -59 mV/pH ($\nu/n = 1$).

NMR spectroscopy

The ¹H NMR spectra of betalains were recorded using a Bruker Avance III 500 (11.7 T) spectrometer, operating at 500 MHz, using a 5-mm triple resonance probe (TXI) with inverse detection, at 293 K, and the *zg30* pulse program (30° flip angle). Baseline correction was performed using the Whittaker smoother algorithm as implemented in the MestReNova software (v.8.1.4, 2013, Mestrelab Res.). Samples were prepared in CD₃OD (700 μL)

immediately before spectral acquisition at a concentration of 4.0 mg mL⁻¹. Chemical shifts are reported as δ values (ppm) referenced to sodium trimethylsilyl propionate-d₄ (TSP) signal, δ_{H} (TSP, *s*) = 0 ppm. Multiplicities were given as *s* (singlet); *brs* (broad singlet); *d* (doublet); *t* (triplet); *m* (multiplet) and, *dd* (double of doublets). Due to limited solubility and low persistence of these betalains in D₂O and in other polar solvents, ¹³C NMR data could not be obtained.

HPLC-DAD-ESI(+)-MS/MS analyses

Experiments were carried out on an Bruker Daltonics Esquire HCT ion trap mass spectrometer equipped with an electrospray source and coupled to a Shimadzu Prominence LC-20AD liquid chromatograph equipped with a Kinetex EVO C18 column (150 mm × 4.6 mm, 5 μ m, Phenomenex) maintained at 25 °C, and a PDA SPD-M20A detector. Nitrogen was used as nebulizing (45 psi) and drying gas (6 L min⁻¹, 325 °C) and helium as buffer gas (4 × 10⁻⁶ mbar). The capillary high voltage was set to 4 kV. To avoid space-charge effects, smart ion charge control (ICC) was set to the arbitrary value of 50,000. LC analysis conditions: linear gradient from 5% to 20% B in 8 min and 20 to 50% B from 8 to 10 min, at 25 °C; solvent systems, A: water with formic acid (0.05% v/v); B: 0.05% v/v formic acid in MeCN/water (60/40); flow rate: 0.3 mL min⁻¹, injection volume: 10 μ L.

Supplementary Figures and Table

Figure S1. ^1H NMR spectrum (500 MHz, CD_3OD) of pBeet. The interval between 4.6 – 4.8 ppm (residual water signal) is not shown for clarity. The multiplicity of poorly-resolved peaks were inferred by using non-linear data fitting (blue curves).

Figure S2. ESI(+)-MS spectrum of pBeet (exact mass: 287.1026 amu) and MS/MS spectrum of the precursor ion m/z 287.1.

Figure S3. ^1H NMR spectrum (500 MHz, CD_3OD) of mepBeet. The interval between 4.6 – 4.8 ppm (residual water signal) is not shown for clarity. The multiplicity of poorly-resolved peaks were inferred by using non-linear data fitting (blue curves).

Figure S4. ESI(+)-MS spectrum of mepBeet (exact mass: 301.1183 amu) and MS/MS spectrum of the precursor ion m/z 301.1.

Figure S5. ^1H NMR spectrum (500 MHz, CD_3OD) of *m*-OH-pBeet. The interval between 4.6 – 4.8 ppm (residual water signal) is not shown for clarity. The multiplicity of poorly-resolved peaks were inferred by using non-linear data fitting (blue curves).

Figure S6. ESI(+)-MS spectrum of *m*-OH-pBeet (exact mass: 303.0975 amu) and MS/MS spectrum of the precursor ion m/z 303.1.

Figure S7. ^1H NMR spectrum (500 MHz, CD_3OD) of *m*-OH-mepBeet. The interval between 4.6 – 4.8 ppm (residual water signal) is not shown for clarity. The multiplicity of poorly-resolved peaks were inferred by using non-linear data fitting (blue curves).

Figure S8. ESI(+)-MS spectrum of *m*-OH-mepBeet (exact mass: 317.1132 amu) and MS/MS spectrum of the precursor ion m/z 317.2

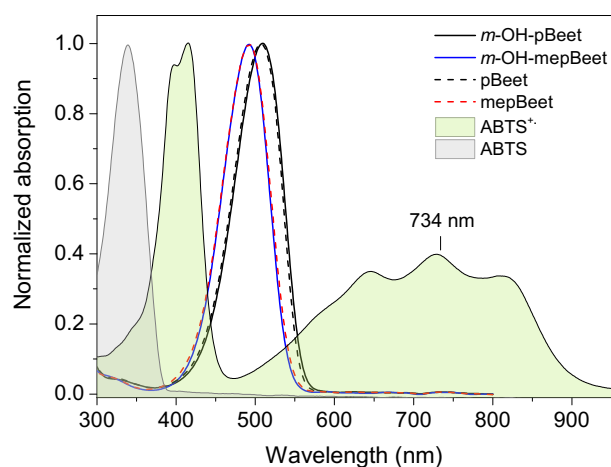

Figure S9. Normalized absorption spectra of pBeets, mepBeets and $\text{ABTS}^{+\bullet}$ in water.

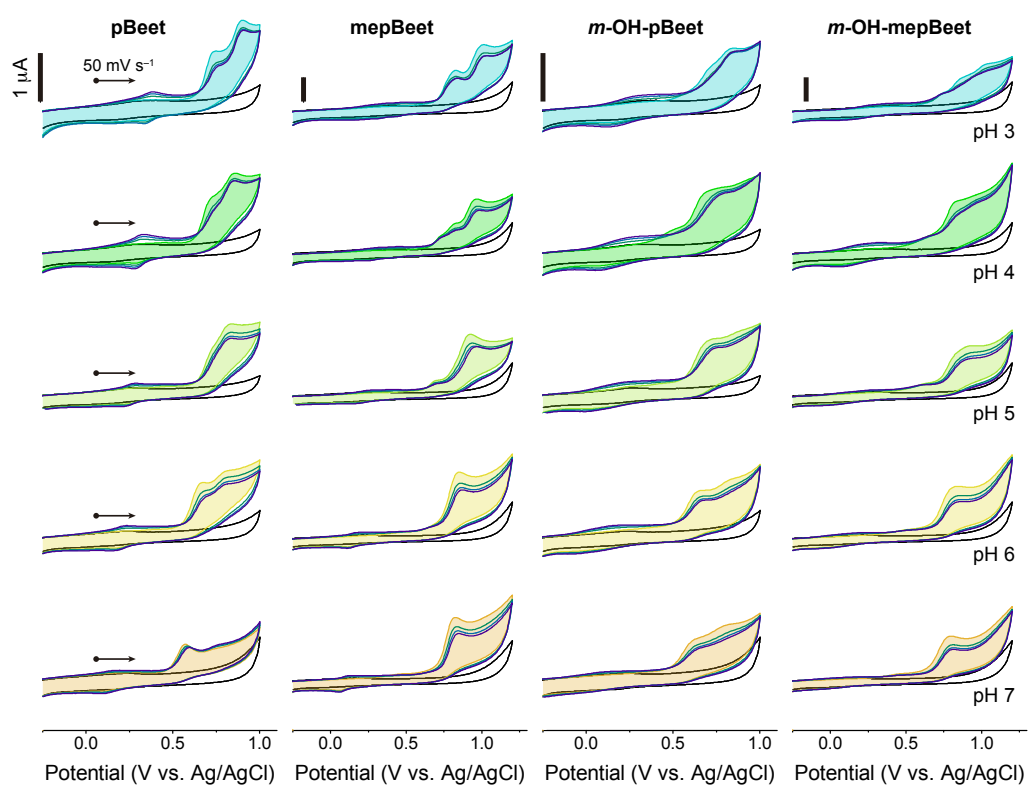

Figure S10. Cyclic voltammograms of pBeets and mepBeets in BR buffer at pH ranging from 3 to 7. Glassy carbon electrode; $\text{Ag}|\text{AgCl}$ (KCl sat.); scan rate: 50 mV s^{-1} , potential range: -1.0 to 1.0 V or -1.0 to 1.25 V; $[\text{betalain}] = 0.1 \text{ mmol L}^{-1}$.

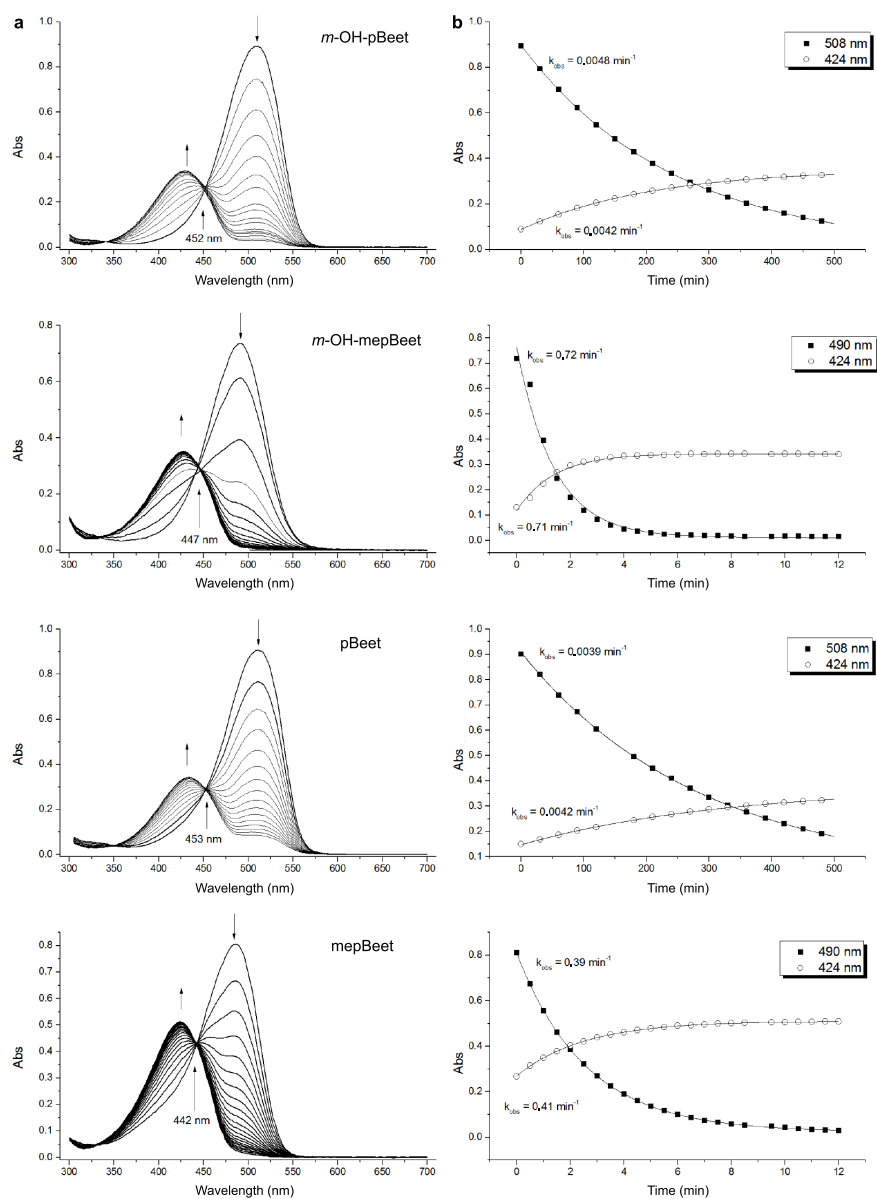

Figure S11. Hydrolysis of pBeet, mepBeet, *m*-OH-pBeet and *m*-OH-mepBeet. (a) Absorption spectra of betalains in BR buffer (pH 7 or 11, 40 mmol L⁻¹). (b) Kinetics of betalain hydrolysis and betalamic acid formation, as inferred from changes in absorption at roughly 500 nm and 424 nm, respectively. The observed rate constants (k_{obs}) were calculated by non-linear curve fitting of the experimental data to a monoexponential function.

Table S1. TEAC values \pm sd of the pBeets and the mepBeets measured after 6 – 120 min of reaction.
