eAppendix 1. Identification of Opioids and Conversion to Morphine Milligram Equivalents

We identified all opioid drugs present in the table of NDC codes in OptumLabs Data Warehouse. For the purposes of this analysis, we classified tramadol as an opioid. To limit the sample to drugs intended for home use, we excluded any injected or infused drug—those for which the dosage form was vial, syringe, ampule, cartridge, IV solution, etc. We included only drugs which had a defined dose unit like a tablet, pill, mg/mL, etc. This excludes drugs in powder or bulk form. We included both single drug formulations and combinations of drugs. eTable 1 includes all opioid drug combinations found in the table of NDC codes. Both long-acting and short-acting formulations were included. Conversion factors were taken from the CDC compilation.¹

eAppendix 2. Details of the Statistical Analysis Methodology

Changes in coprescribing were analyzed both as a one-time change in level at the time of CDC guideline release and as a change in trend after the guideline release. To implement this approach, piecewise regression with a single knot spline was used and three main exposure variables were created. The variables *PreRelease* and *Release* were components of a spline with a knot at the release of the guidelines (March 2016). *PreRelease* measured the trend in the outcome variable before the intervention, while *Release* captured the change in trend after the intervention. *AfterRelease* was an indicator for time after March 2016. This indicator was used to measure the change in level of the outcome variable from just before to just after the guidelines release.

The unit of observation for the analysis of the extent of coprescription was a person-month during which the beneficiary had opioids available for at least one day; the unit of observation for the analysis of the intensity of coprescription was a person-month during which

the beneficiary had at least one day of overlapping opioids and benzodiazepines.. A generalized linear model was specified with clustered standard errors to account for repeated observations on the same patients. The model was adjusted for beneficiary covariates age, sex, race/ethnicity, state of residence, and a series of indicator variables for each of the Elixhauser comorbidities² measured on a rolling 6 month basis. A logit specification was used to assess the extent of coprescription, while a negative binomial specification was used to assess intensity of coprescription. In the latter model, the natural log of the number of opioid days was included with the coefficient constrained to 1 to allow interpretation of the incidence rates as the proportion of overlapping days of opioids and benzodiazepines. In the main analyses of intensity and extent of coprescribing, separate models were estimated for the two beneficiary insurance populations (commercial and MA) and two types of opioid use episodes (long-term and short-term). For the subanalysis of coprescribing extent by race and ethnicity, commercial and MA populations were modeled together, with a binary variable indicating population added to the model.

In a sensitivity analysis, coprescribing by the same physician was further explored in comparison to one physician prescribing the benzodiazepine and another prescribing the opioid. This specification included interactions of the three main exposure variables with a categorical variable measuring whether the same physician prescribed the opioids and benzodiazepines; this model was limited to person-months with any overlap days. The categorical variable could take the following values; (1) at least one day of overlap with prescriptions written by different physicians; (2) at least one day of overlap with prescriptions written by the same physician; (3) at least one day of overlap, but it was not possible to assess whether the same physician prescribed the drugs because of unknown prescriber identification numbers on one or both of the

prescriptions. Some beneficiaries had multiple opioid and multiple benzodiazepine prescriptions available in the same month. In those cases, if there was at least one pair of overlapping opioid and benzodiazepine prescriptions from the same physician, the categorical variable was set to “same physician.” A truncated negative binomial model was used because the outcome distribution could not take the value 0.

A post-hoc sensitivity analysis was specified to assess initiation of benzodiazepines in the first 90 days of new long-term opioid use episodes that began before the guideline release versus those that began after the guideline release. Separate models were specified for commercial and Medicare Advantage populations.

The Holm sequentially rejective multiple test procedure was used to control the family-wise error rate at 0.05.³ Tables, text, and figures denote with asterisks whether comparisons are statistically significant after this adjustment. For the purpose of controlling the error rates, the analyses of extent and intensity of coprescribing were treated as a single family of analyses, as were the analyses of same physician prescribing, the analyses by race and ethnicity, and the analyses of long-term episodes beginning before and after the guideline release.

Summary statistics are presented as percent and standard error (SE) for categorical variables, and as median and interquartile range (IQR, 25th percentile, 75th percentile) for continuous variables.

Complete regression results are available in the Supplementary Appendix Tables S3-S7 and S14 along with further detail on model specifications. Figures present adjusted rates of overlapping opioid and benzodiazepine fills, and adjusted proportion of opioid days where benzodiazepines were also available (overlap days), with 95 confidence intervals in tables;

unadjusted values are plotted along with lines representing the adjusted rates. All analyses were performed with Stata/MP version 15.0.⁴

eAppendix 3. Elixhauser Comorbidity Calculations

ICD 9 and 10 codes from Quan et al.² were used to define the Elixhauser comorbidities. We created flags for the presence of at least one inpatient or two outpatient dates of service with a diagnosis from the Elixhauser definitions. Flags were created for each month, looking back at the prior 6 months of health care service use. The flags were set to 1 if the definition was met, or 0 if it was not. A separate flag was created to indicate whether the beneficiary had not had 6 prior months of coverage and was included separately in the models.

eAppendix 4. Cancer

To exclude beneficiaries with cancer, we looked for at least 2 evaluation and management procedure codes on different dates of service where one of the first 4 diagnoses on the claim was a cancer diagnosis. An opioid episode was excluded if the beneficiary had at least 2 cancer evaluation and management claims during the period from 3 months before the start of the episode through the end of the episode. The codes used to define cancer for the purpose of excluding opioid use episodes were ICD9 codes 140 through 209, ICD9 codes 230 through 239, ICD10 codes C00 through C97, ICD10 codes D00 through D09, and ICD10 codes D37 through D47.

eAppendix 5. Sickle Cell Disease

To exclude beneficiaries with sickle cell disease, we used the same procedure as used to exclude episodes for cancer. The codes used to define sickle cell disease were ICD9 codes 282.41, 282.42, 282.6x;⁵ and ICD10 codes D570.x, D571.x, D574.x, and D578.x.

eAppendix 6. Hospice

We excluded any opioid use episode with one or more hospice procedure or revenue codes during the period from 3 months before the start of the episode through the end of the episode. Hospice procedure codes were 99377, 99378, G0182, G0337, G9474-G9479, G9524, Q5001-Q5010, S0255, S9126, and T2042-T2046. Hospice revenue codes were 0115, 0125, 0135, 0145, 0155, 0235, and 065x.

eTable 6. Adjusted Estimates: Extent and Intensity of Coprescription

Population Opioid episode type		Commercially insured		Medicare Advantage	
		Long-term	Short-term	Long-term	Short-term
		Value (95% CI)	Value (95% CI)	Value (95% CI)	Value (95% CI)
Extent of coprescription: Adjusted percent of overlapping opioids and BZDs in month					
Adjusted percent of people with overlapping opioids and BZDs in month	Study start	22.07 (21.26 to 22.87)	8.83 (8.75 to 8.90)	24.42 (23.56 to 25.28)	13.52 (13.36 to 13.69)
	Just before guideline	23.20 (22.62 to 23.78)	9.24 (9.16 to 9.31)	26.78 (26.16 to 27.41)	14.47 (14.31 to 14.63)
	Just after guideline	24.08 (23.49 to 24.66)	8.98 (8.90 to 9.07)	26.65 (26.06 to 27.24)	13.45 (13.30 to 13.60)
	Study end	22.18 (21.49 to 22.86)	8.88 (8.79 to 8.97)	24.53 (23.98 to 25.09)	14.39 (14.24 to 14.54)
Intensity of coprescription: Adjusted percent of opioid days with concurrent BZDs					
Adjusted percent of opioid days that also have BZDs available	Study start	78.36 (77.53 to 79.18)	79.03 (78.77 to 79.29)	82.62 (81.90 to 83.35)	82.62 (81.90 to 83.35)
	Just before guideline	79.60 (79.02 to 80.17)	79.44 (79.19 to 79.69)	83.83 (83.33 to 84.32)	83.83 (83.33 to 84.32)
	Just after guideline	79.51 (78.94 to 80.09)	79.13 (78.85 to 79.42)	83.50 (83.04 to 83.96)	83.50 (83.04 to 83.96)
	Study end	80.05 (79.33 to 80.77)	79.73 (79.41 to 80.04)	85.18 (84.74 to 85.62)	85.18 (84.74 to 85.62)

Adjusted percentages represent predictive margins from a logit or zero-truncated negative binomial model that included patient age, sex, race/ethnicity, state of residence, and Elixhauser comorbidity flags calculated on a rolling 6 month basis. Separate models were specified for each patient population and episode type (commercial and Medicare Advantage; long-term and short-term). Standard errors in the model were adjusted for clustering on individual patient.

BZD=benzodiazepine

eTable 15. Intensity of Coprescribing Before and After the Guideline Release: Comparing Same Physician Prescribing to Different Physicians Prescribing Opioids and Benzodiazepines

Coprescribing type	Population Opioid episode type	Commercially insured				Medicare Advantage			
		Long-term		Short-term		Long-term		Short-term	
		Value (95% CI)		Value (95% CI)		Value (95% CI)		Value (95% CI)	
Coprescribing intensity: Percent of opioid days in month with benzodiazepines available									
Same physician prescribing opioids and benzodiazepines	Before the guideline	80.51 (80.04 to 80.99)		75.09 (74.87 to 75.30)		84.54 (84.12 to 84.95)		83.42 (83.20 to 83.64)	
	After the guideline	81.39 (80.91 to 81.87)		75.68 (75.44 to 75.91)		86.00 (85.67 to 86.33)		84.31 (84.11 to 84.50)	
Different physicians prescribing opioids and benzodiazepines	Before the guideline	76.65 (76.02 to 77.27)		78.34 (78.13 to 78.55)		81.53 (80.96 to 82.10)		81.93 (81.67 to 82.19)	
	After the guideline	77.45 (76.86 to 78.04)		78.24 (78.00 to 78.47)		81.79 (81.33 to 82.26)		82.24 (82.01 to 82.47)	
Unknown	Before the guideline	72.94 (70.79 to 75.08)		70.74 (70.20 to 71.28)		79.36 (78.17 to 80.54)		81.04 (80.44 to 81.64)	
	After the guideline	73.73 (71.66 to 75.81)		70.79 (70.22 to 0.00)		81.77 (80.99 to 82.55)		81.58 (81.15 to 82.01)	
Absolute difference in coprescribing intensity (base level = Different physicians; positive difference indicates group has higher coprescribing intensity than those receiving opioids and benzodiazepines from different physicians)									
Same physician prescribing opioids and benzodiazepines	Before the guideline	3.87 (3.11 to 4.62) ^b		-3.25 (-3.55 to -2.96) ^b		3.01 (2.33 to 3.69) ^b		1.49 (1.16 to 1.82) ^b	
	After the guideline	3.94 (3.20 to 4.69) ^b		-2.56 (-2.88 to -2.23) ^b		4.21 (3.66 to 4.76) ^b		2.07 (1.77 to 2.37) ^b	
Unknown	Before the guideline	-3.71 (-5.91 to -1.51) ^b		-7.60 (-8.18 to -7.02) ^b		-2.17 (-3.46 to -0.89) ^b		-0.89 (-1.54 to -0.24) ^b	
	After the guideline	-3.72 (-5.84 to -1.59) ^b		-7.44 (-8.06 to -6.83) ^b		-0.02 (-0.90 to 0.85)		-0.66 (-1.15 to -0.17) ^b	
Adjusted percentages represent predictive margins from a zero-truncated negative binomial model that included patient age, sex, race/ethnicity, state of residence, and Elixhauser comorbidity flags calculated on a rolling 6 month basis. Separate models were specified for each patient population and episode type (commercial and Medicare Advantage; long-term and short-term). Standard errors in the model were adjusted for clustering on individual patient.									
Absolute differences are in percentage points									
^b Difference statistically significantly different than 0 after controlling for family-wise error rate of 0.05 within table									

eTable 16. Extent of Coprescription by Race/Ethnicity: Adjusted Percent of Overlapping Opioids and BZDs in Month

Race/ethnicity	White	Black	Hispanic	Asian	Unknown/other
	Value (95% CI)	Value (95% CI)	Value (95% CI)	Value (95% CI)	Value (95% CI)
	Long-term opioid use episodes				
Study start	24.31 (23.62 to 25.01)	19.53 (18.01 to 21.04)	22.08 (20.04 to 24.12)	19.62 (14.42 to 24.82)	23.50 (19.40 to 27.61)

p-value (change in slope=0)	0.266	0.054	0.006	0.283	0.527

Adjusted rates of overlapping opioid and benzodiazepine fills represent predictive margins from a logit model that included patient age, sex, race/ethnicity, state of residence, and Elixhauser comorbidity flags calculated on a rolling 6 month basis. Adjusted rates of opioid days with benzodiazepines were specified with the same covariates, but were negative binomial models using the number of opioid days in the month as an exposure variable (i.e., the natural log of opioid days was included in the model with the coefficient constrained to be 1). Separate models were specified for each patient population (commercial, Medicare Advantage). Standard errors in the model were adjusted for clustering on individual patient. BZD=benzodiazepine

^a Slopes given in units of percentage point change per 12 months

^b Statistically significant after controlling for family-wise error rate of 0.05 within table

Adjusted rates of overlapping opioid and benzodiazepine fills represent predictive margins from a logit model that included patient age, sex, race/ethnicity, state of residence, and Elixhauser comorbidity flags calculated on a rolling 6 month basis. Separate models were specified for each patient population and episode type (commercial and Medicare Advantage; long-term and short-term). Standard errors in the model were adjusted for clustering on individual patient.

^a Slopes given in units of percentage point change per 12 months

^b Statistically significant after controlling for family-wise error rate of 0.05 within table

eTable 23. Adjusted Coprescribing Extent Estimates and Trends in Long-term Opioid Use Episodes Starting Before vs After the Guidelines Were Released

	Com	MA
	Proportion of long-term opioid use episodes with opioid/benzodiazepine coprescribing in the first 90 days of the episode	
Study start	28.60% (27.58% to 29.62%)	29.09% (28.11% to 30.07%)
Just before guideline	27.61% (26.60% to 28.62%)	29.58% (28.61% to 30.54%)
Just after guideline	29.16% (27.86% to 30.45%)	29.63% (28.64% to 30.63%)
Study end	26.95% (25.26% to 28.64%)	27.06% (25.88% to 28.23%)

	Com	MA
Change in level (percentage points)	1.55% (-0.09 to 3.19)	0.06% (-1.34% to 1.45%)
p-value (change in level=0)	0.0642	0.9378
pre-guideline release slope ^a	-0.46% (-1.26% to 0.34%)	0.22% (-0.54% to 0.99%)
post-guideline release slope ^a	-1.11% (-2.45% to 0.24%)	-1.29% (-2.26% to -0.32%)
p-value (change in slope=0)	0.415	0.0164
<p>Adjusted rates of having overlapping opioid and benzodiazepine fills in the first 90 days of an incident long-term opioid use episode represent predictive margins from a logit model that included patient age, sex, race/ethnicity, state of residence, and Elixhauser comorbidity flags calculated on a rolling 6 month basis. The unit of observation was a long-term opioid use episode; episodes were included in the month in which they started. Separate models were specified for each patient population (commercial, Medicare Advantage). Standard errors in the model were adjusted for clustering on individual patient.</p> <p>^a Slopes given in units of percentage point change per 12 months</p>		

eFigure 1. Cohort Flow Chart Describing Construction of the Study Sample

eFigure 2. Race/Ethnicity: Coprescribing Extent

n.s. not statistically significant with family-wise error rate 0.05 across analyses in figure; * statistically significant at $p=0.05$. Statistical significance for change in level indicated next to line demarking release of opioid guidelines. Statistical significance for change in trend (line slope) indicated to the right of the statistical significance of the change in level. The plotplain package was used to display the figure.

eFigure 3. Coprescribing Extent by Opioid Dose

— <20 MME - - - 20 to 50 MME - · - 50 to 90 MME

— 90 to 120 MME - - - >=120 MME

n.s. not statistically significant with family-wise error rate 0.05 across analyses in figure; * statistically significant at $p=0.05$. Statistical significance for change in level indicated next to line demarking release of opioid guidelines. Statistical significance for change in trend (line slope) indicated to the right of the statistical significance of the change in level. The plotplain package was used to display the figure.
