

Supplementary Information

Molecular Mass Growth Processes through Ring Expansion in Polycyclic Aromatic Hydrocarbons via Radical-Radical Reactions

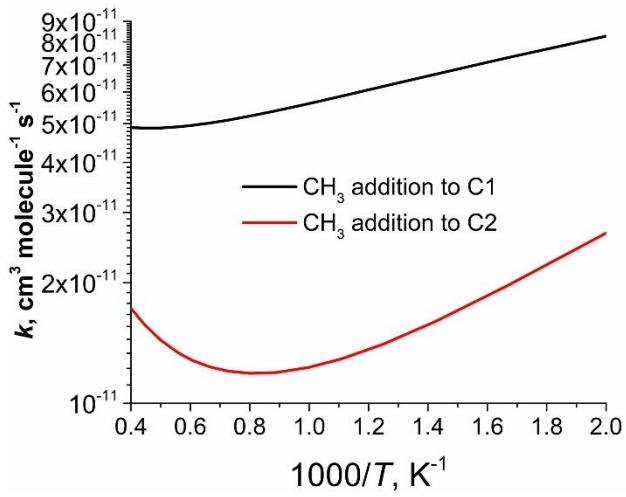

Zhao et al.

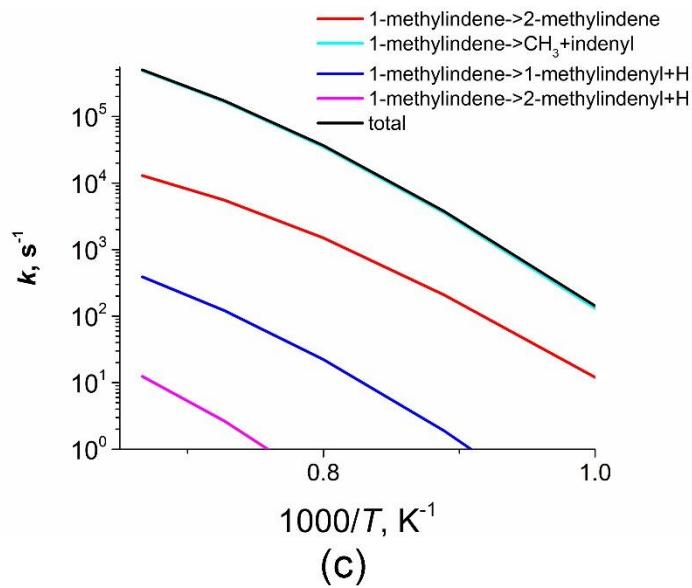

Supplementary Figure 1. Potential energy diagram for the indenyl + methyl reaction calculated at the CCSD(T)-F12/cc-pVTZ-f12//B3LYP/6-311G(d,p) + ZPE[B3LYP/6-311G(d,p)] level of theory. All relative energies are given in kJ/mol.

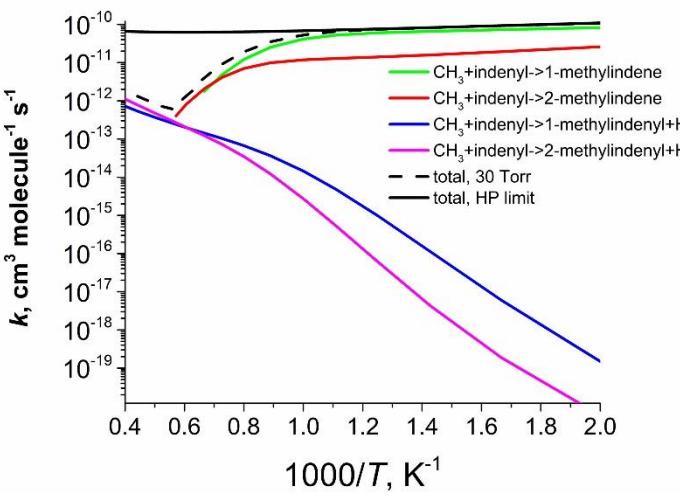

Supplementary Figure 2. Potential energy diagram for unimolecular decomposition of methylindenyl radicals calculated at the G3(CC,MP2)//B3LYP/6-311G(d,p) + ZPE[B3LYP/6-311G(d,p)] level of theory. All relative energies are given in kJ/mol. For more detail on this PES and temperature- and pressure-dependent rate constants see Ref. 22 in the main text.

(c)

(b)

(d)

Supplementary Figure 3.

- (a) High-pressure limit rate constants for CH_3 addition to C1/C3 vs. C2 in indenyl. In the entrance channel, the addition to C1/C3 is favored, by a factor of ~4 at T about 1400 K, i.e., in the reactor's temperature range.
- (b) Total and individual channel rate constants at 30 Torr (the typical pressure inside the reactor). Fitted modified Arrhenius expressions for all relevant reactions in the indenyl + CH_3 system calculated at various pressures up to 100 atm (for combustion applications) are presented in Table S1. There is a competition between collisional stabilization of 1- and 2-methylindene and the formation of bimolecular 1-/2-methylindenyl + H products. The calculated product branching ratios at 30 Torr are shown in Table S2. In the 1375-1500 K temperature range, collisionally stabilized 1- and 2-methylindene are predicted to be the predominant products with nearly equal yields, whereas the contribution of 1-/2-methylindenyl + H via well skipping pathways is only few percent.
- (c) Unimolecular rate constants for isomerization/dissociation of 1-methylindene at 30 Torr.
- (d) Unimolecular rate constants for isomerization/dissociation of 2-methylindene at 30 Torr.

Both methylindenes preferably decompose back to the reactants and the second most probable channel for each is isomerization to one another followed by H loss to 1- and 2-methylindenyl radicals, respectively. According to the calculated rate constants, 2-methylindene is more stable with the equilibrium constant for $1\text{-methylindene} \rightarrow 2\text{-methylindene}$ being ~4.5 in the microreactor's temperature range. Therefore, 2-methylindene should be significantly more abundant on the exit from the reactor in agreement with the PIE fit for $m/z = 131$.

Source data are provided as a Source Data file.

Supplementary Table 1. Rate constant parameterization using modified Arrhenius expressions $k = A_1*T^{\alpha_1}*\exp(-E_1/T) + A_2*T^{\alpha_2}*\exp(-E_2/T)$.

Pre-exponential factors A are in $\text{cm}^3 \text{molecule}^{-1} \text{s}^{-1}$ for bimolecular reactions and in s^{-1} for unimolecular reactions, T in K.

Supplementary Note 1. Synthetic Procedure:

1-Bromoindene was synthesized using the procedure described in detail in our previous publication.¹

Supplementary Figure 4. Complete mass spectra recorded at a photon energy of 9.50 eV; the source temperature was 1425 ± 10 K. (a) 1-indenyl/helium, (b) 1-indenyl/ methyl, (c) 1-indenyl/D₃-methyl. Source data are provided as a Source Data file.

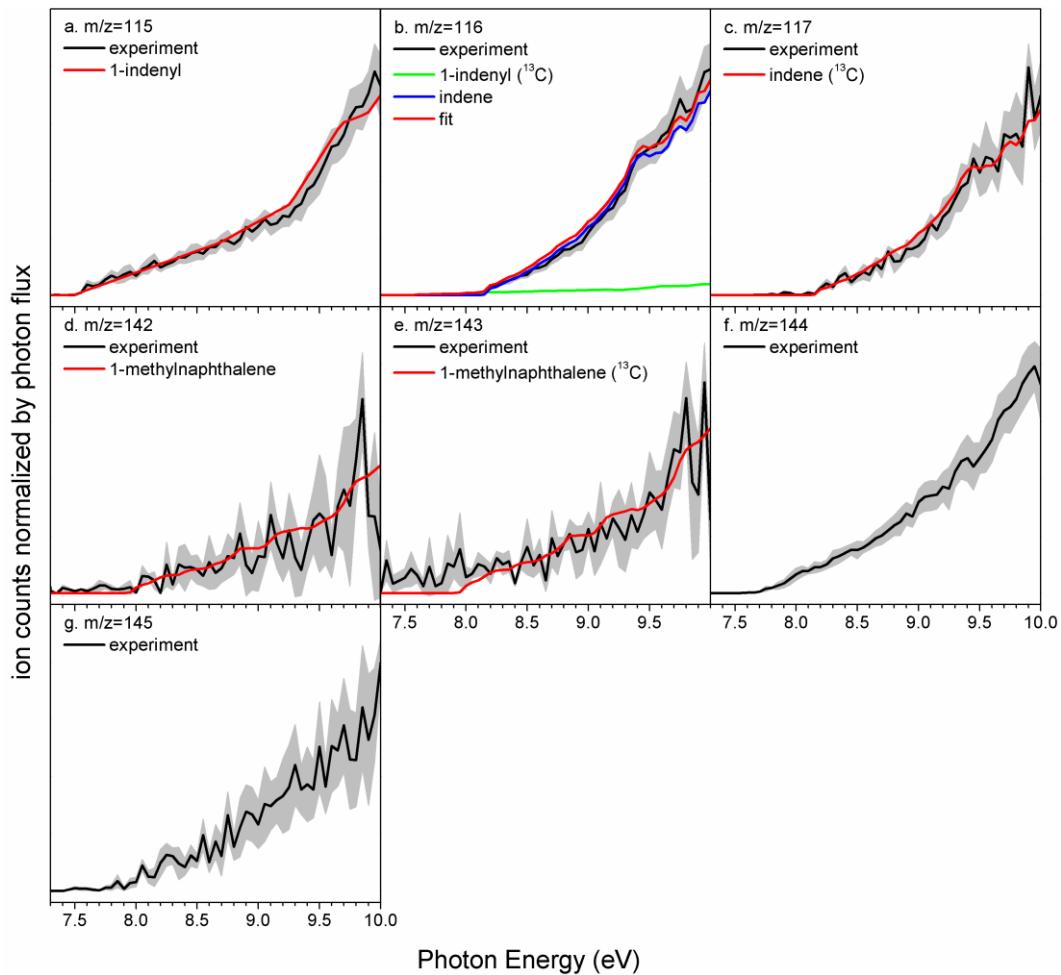

Supplementary Figure 5. Mass spectra recorded at a photon energy of 9.50 eV; the source temperature was 1425 ± 10 K. (a) acetone/helium, (b) D6-acetone/helium.

In both acetone – helium and D6-acetone – helium systems, helium was observed at $m/z = 4$, with a photoionization energy of 24.6 eV,² due to the high harmonics of VUV light and the high concentration of helium. In the acetone – helium system, another three strong peaks at $m/z = 15$, 43 and 58 are detected. Signal at $m/z = 58$ is attributed to acetone (CH_3COCH_3). With the C-C bond scission, acetone is decomposed to acetyl ($\text{CH}_3\text{CO}^\cdot$) and methyl (CH_3^\cdot) radicals, which are at $m/z = 15$ and 43. The species at $m/z = 42$ should be ketene (CH_2CO), the H-loss product of acetyl radical.

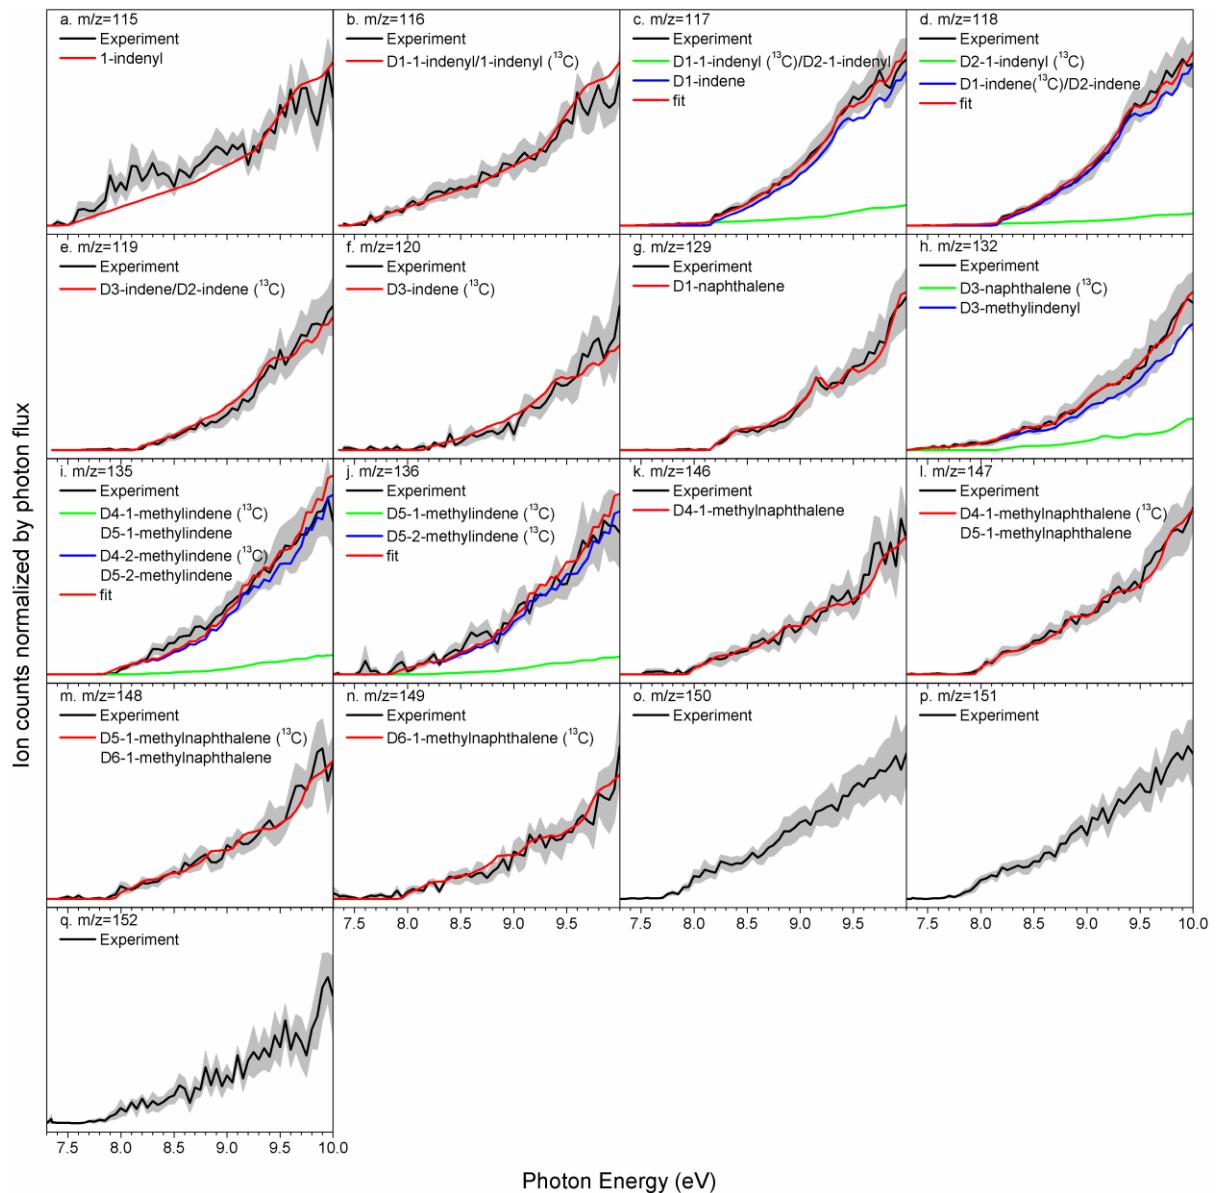

In the D6-acetone – helium system, strong signal at $m/z = 18$, 46 and 64 is observed. Similar as that in the acetone – helium system, these three peaks are attributed to D3-methyl (CD_3^\cdot), D3-acetyl ($\text{CD}_3\text{CO}^\cdot$) and D6-acetone (CD_3COCD_3), respectively, with the previous two generated from the C-C scission of D6-acetone. Analogously, D2-ketene (CD_2CO , $m/z = 44$) is produced via D-loss of D3-acetyl. For other small signal masses, as the goal in this work is to investigate the indenyl – methyl reaction, they are not discussed in detail here.

Source data are provided as a Source Data file.

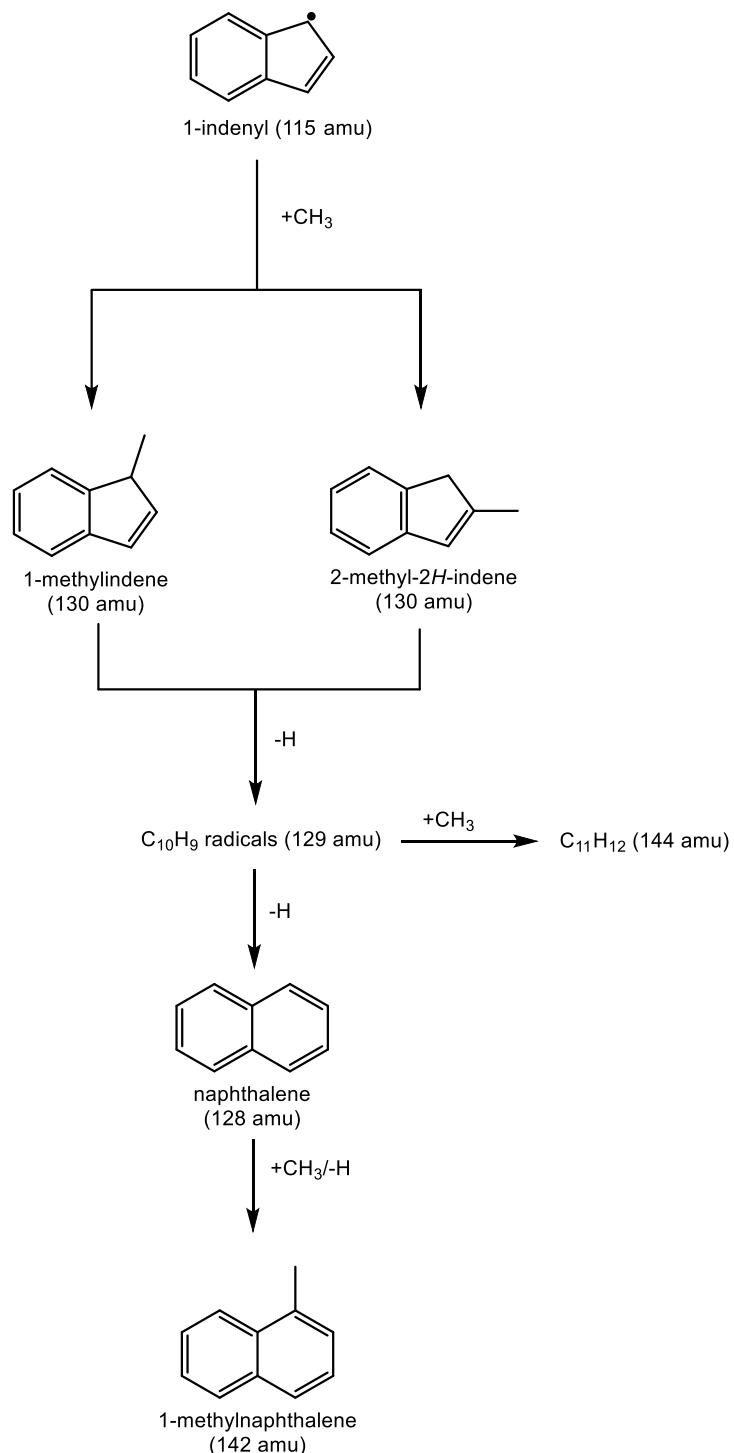

Supplementary Figure 6: PIE curves of additional ion counts detected in the 1-indenyl – methyl system. The detected signals include: (a) $m/z = 115$, (b) $m/z = 116$, (c) $m/z = 117$, (d) $m/z = 142$, (e) $m/z = 143$, (f) $m/z = 144$ and (g) $m/z = 145$. Black: experimental PIE curves; blue/green/red: reference PIE curves. In case of multiple contributions to one PIE curve, the red line resembles the overall fit. The error bars consist of two parts: $\pm 10\%$ based on the accuracy of the photodiode and a 1σ error of the PIE curve averaged over the individual scans.

Source data are provided as a Source Data file.

Supplementary Figure 7: PIE curves of additional ion counts detected in the 1-indenyl – D3-methyl system. PIE fits for signals at (a) $m/z = 115$, (b) $m/z = 116$, (c) $m/z = 117$, (d) $m/z = 118$, (e) $m/z = 119$, (f) $m/z = 120$, (g) $m/z = 129$, (h) $m/z = 132$, (i) $m/z = 135$, (j) $m/z = 136$, (k) $m/z = 146$, (l) $m/z = 147$, (m) $m/z = 148$, (n) $m/z = 149$, (o) $m/z = 150$, (p) $m/z = 151$ and (q) $m/z = 152$ are presented. Black: experimental PIE curves; blue/green/red: reference PIE curves. In case of multiple contributions to one PIE curve, the red line resembles the overall fit. The error bars consist of two parts: $\pm 10\%$ based on the accuracy of the photodiode and a 1σ error of the PIE curve averaged over the individual scans.

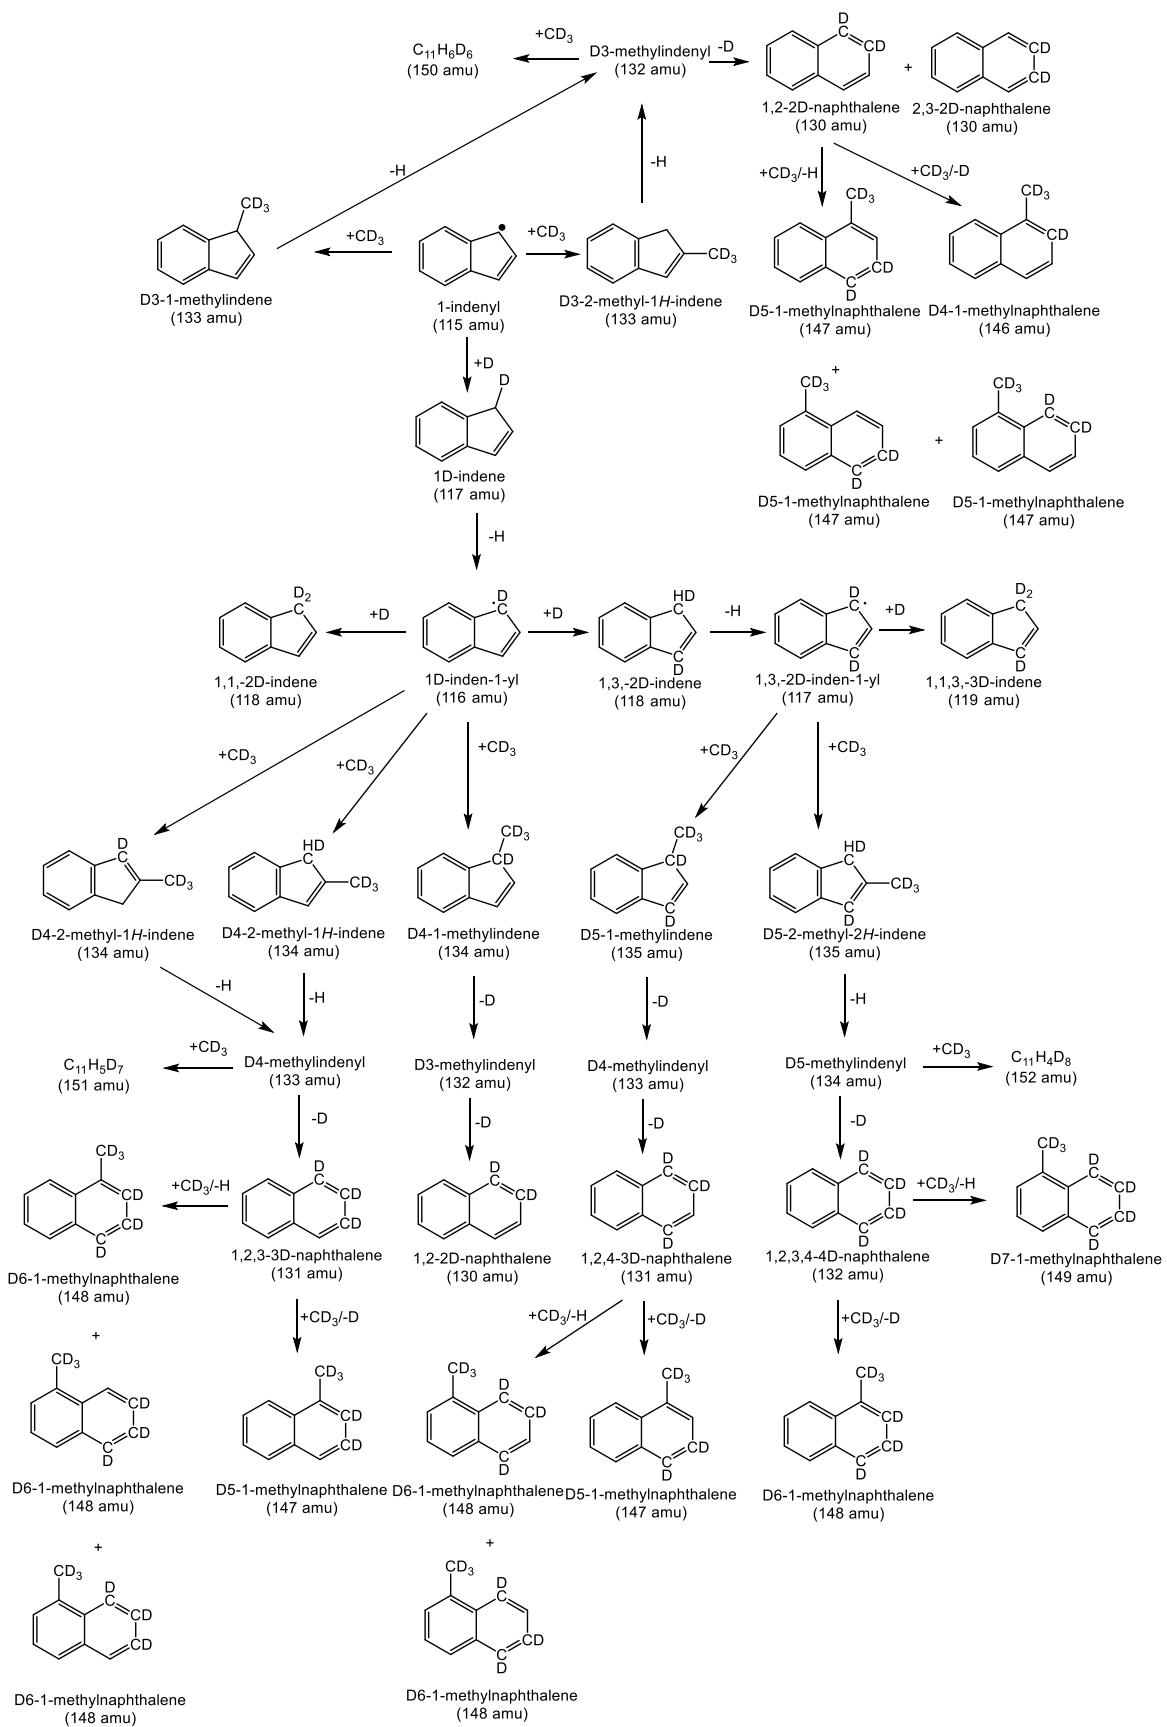

Source data are provided as a Source Data file.

Supplementary Figure 8: Schematic reaction pathways in the 1-indenyl – methyl system to account for ion counts from $m/z = 142$ to 145 .

In the 1-indenyl - methyl system, ion signal from $m/z = 142$ to 145 was also observed. The analysis of the PIE curves reveals that $m/z = 142$ ($\text{C}_{11}\text{H}_{10}^+$) and 143 ($^{13}\text{C}\text{C}_{10}\text{H}_{10}^+$) are attributed to 1-methylnaphthalene and ^{13}C -1-methylnaphthalene, respectively (Supplementary

Figs. 6(d) and (e)). This species might be generated via the reaction of naphthalene with a methyl radical followed by hydrogen atom loss.³ Considering the ion counts at $m/z = 144$ ($C_{11}H_{12}^+$) and 145 ($^{13}CC_{10}H_{12}^+$), the PIE curves overlap after scaling indicating that $m/z = 145$ is the ^{13}C counterpart of $m/z = 144$ (Supplementary Figs. 6(f) and (g)). Considering the molecular weight, this species might be produced via the reaction of methylindene ($C_{10}H_{10}$, $m/z = 130$) and methyl ($CH_3\cdot$, $m/z = 15$) followed by atomic hydrogen loss. However, due to the lack of any reference PIE data for dimethylated indene isomers, $m/z = 144$ and 145 remain unidentified.

Supplementary Figure 9: Schematic reaction pathways in the 1-indenyl – D3-methyl system.

The calculated branching ratios of benzofulvene versus naphthalene at the conditions of our reactor are nearly equal to 4 to 1. Therefore, we expected the bimolecular mechanism, i.e. deuterium (D) loss from methylindenyl to eventually form benzofulvene followed by H-assisted isomerization of the latter to naphthalene, to be the most favorable mechanism. This mechanism is consistent with the isotope-labeling result if benzofulvene re-reacts with D and isomerizes to naphthalene through such D-assisted isomerization. However, it is not consistent if benzofulvene reacts with H rather than with D - then the reaction would produce naphthalene with only one D incorporated ($m/z = 129$). The concentrations of hydrogen and deuterium are expected to be roughly equal because the dissociation of 1- or 2-methylindene produces hydrogen and the dissociation of D3-methylindenyl radicals produces deuterium. Therefore, technically these calculations show that 1/5 of naphthalene is produced via the unimolecular mechanism containing two deuterium atoms; 2/5 of naphthalene is likely produced via the bimolecular mechanism via a deuterium-assisted isomerization of benzofulvene containing also two deuterium atoms; finally, 2/5 of naphthalene are formed via a hydrogen-assisted isomerization of benzofulvene and contain only one deuterium. Therefore, qualitatively speaking, the intensity of the ion counts at $m/z = 130$ are expected to be higher than at $m/z = 129$, which agrees with our experimental findings. Further H/D isotope scrambling involving naphthalene itself, like $H + C_{10}H_6D_2$ (naphthalene) $\rightleftharpoons D + C_{10}H_7D_1$ (naphthalene) is favorable in reverse direction because a C-D bond is stronger than a C-H bond due to the effect of ZPE and thus, the H/D isotope scrambling will additionally boost the $m/z = 130$ peak over $m/z = 129$.

Recall that in the 1-indenyl – methyl system, signal is detected from $m/z = 115$ to 117 (1-indenyl, ^{13}C -1-indenyl/indene and ^{13}C -indene); in the 1-indenyl – D3-methyl system (Supplementary Fig. 7), six distinct peaks were observable from $m/z = 115$ to 120. The fits of the PIE graphs indicate that – as detailed below – these ion counts can be connected with the formation of (deuterium substituted) 1-indenyl radicals and indenes including 1-indenyl, D1- and D2-1-indenyls, D1-, D2- and D3-indenes, as well as their ^{13}C -substituted counterparts (Supplementary Figs. 7(a)-(f)). The 1-indenyl radical ($C_9H_7\cdot$, $m/z = 115$, Supplementary Fig. 7(a)) is produced from the pyrolysis of the precursor 1-bromoindene via homolytic carbon – bromine bond (C-Br) scission. The deuterated 1-indenyl radicals might be generated from 1-indenyl radical via two successive D-addition followed by H-loss. For instance, the D-addition to 1-indenyl generates 1D-indene (C_9H_7D , $m/z = 117$, Supplementary Fig. 7(c)), followed by H-loss via either bond scission or H/D-exchange leading to the formation of 1D-

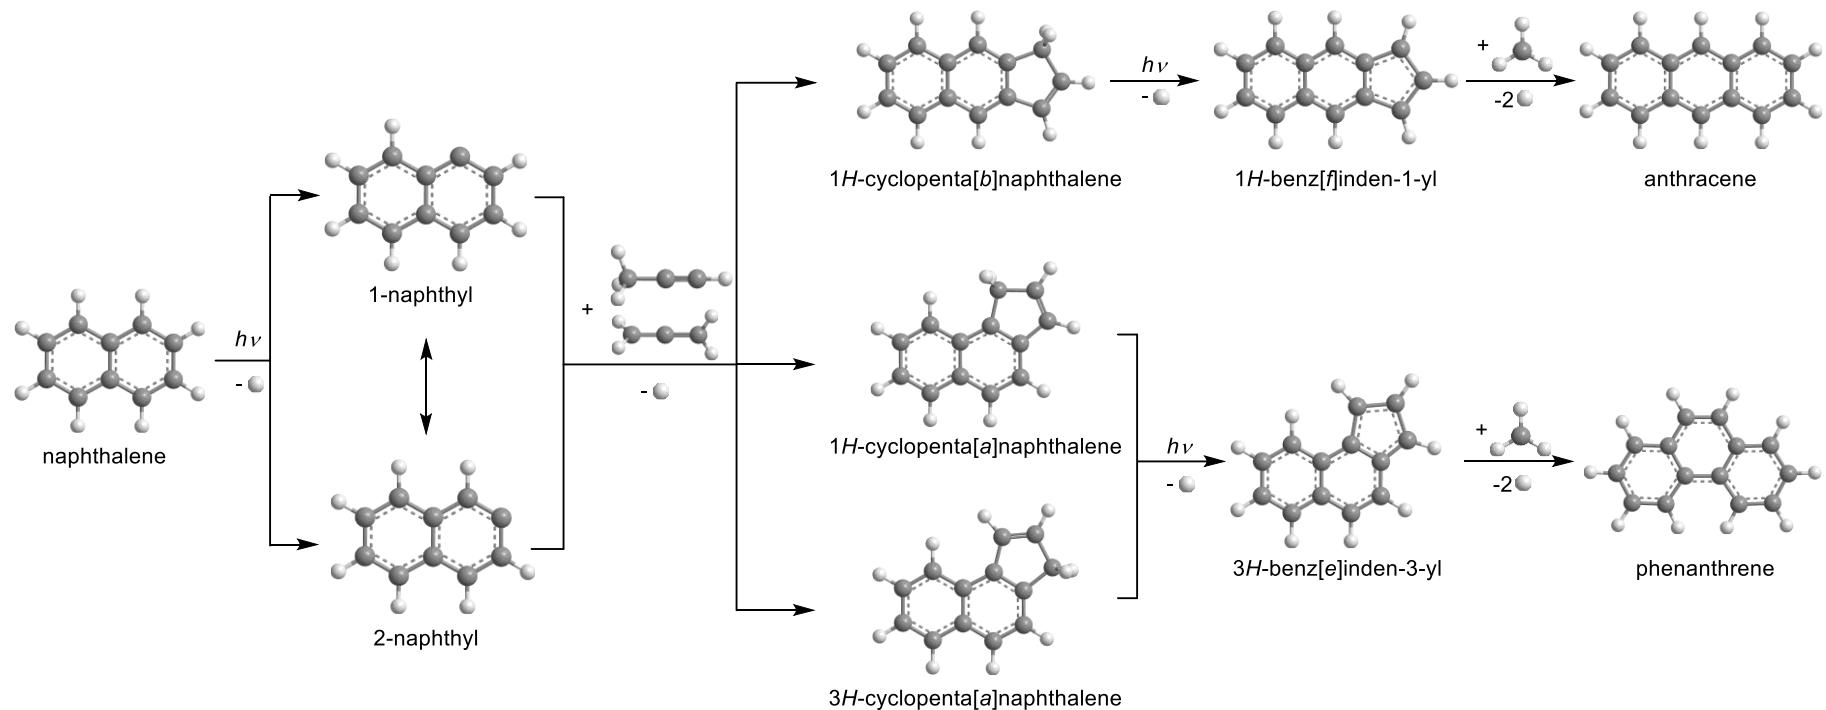

inden-1-yl ($C_9H_6D^\bullet$, $m/z = 116$, Supplementary Fig. 7(b)). Furthermore, combination of 1D-inden-1-yl and D atom yields D2-indenes including 1,1-2D-indene and 1,3-2D-indene ($C_9H_6D_2$, $m/z = 118$, Supplementary Figs. 7(d) and S9).⁴ Analogously, 2D-indenyl radicals ($C_9H_5D_2^\bullet$, $m/z = 117$, Supplementary Fig. 7(c)) and 3D-indene ($C_9H_5D_3$, $m/z = 119$, Supplementary Fig. 7(e)) are produced in the subsequent reactions. The signal at $m/z = 120$ is attributed to the ^{13}C 3D-indene ($^{13}CC_8H_5D_3$, Supplementary Fig. 7(f)).

The reactions of the 1-indenyl radicals with D3-methyl result in D2-, D3-, D4-naphthalenes ($C_{10}H_6D_2$, $m/z = 130$, Fig. 3(e); $^{13}CC_9H_6D_2/C_{10}H_5D_3$, $m/z = 131$, Fig. 3(f); $^{13}CC_9H_5D_3/C_{10}H_4D_4$, $m/z = 132$, Supplementary Fig. 7(h)) and D3-, D4-, D5-substituted 1- and 2-methylindenes ($C_{10}H_7D_3$, $m/z = 133$, Fig. 3(g); $^{13}CC_9H_7D_3/C_{10}H_6D_4$, $m/z = 134$, Fig. 3(h); $^{13}CC_9H_6D_4/C_{10}H_5D_5$, $m/z = 135$, Supplementary Fig. 7(i)). Signal at $m/z = 136$ is related to ^{13}C -D5-1-methylindene and ^{13}C -D5-2-methylindene ($^{13}CC_9H_5D_5$, Supplementary Fig. 7(j)). Note that D3-methylindenyl radical also contributes to the signal at $m/z = 132$ (Fig. S7(h)). Please also note the signal at $m/z = 129$ (Supplementary Fig. 7(g)) is attributed to D1-naphthalene. The reaction of 1-indenyl plus deuterium forming D1-indene followed by decomposition to D1-indenyl plus atomic hydrogen is exoergic because the C-H bond is weaker than the C-D bond due to the effect of zero-point vibrational energy. The relatively strong signals of the deuterated indenyl radicals (Supplementary Figures 4c and 7) also suggest the existence of D1-1-indenyl radical, one of the precursors of D4-methylindene. These bimolecular reactions show the potential formation processes for deuterated indenyl radicals, and they do not go against the fact that naphthalene is formed via a 1-indenyl - methyl recombination followed by H-loss steps. Just like the formation of D3-methylindene via the reaction of 1-indenyl with D3-methyl, D4-methylindene is produced via the reaction of D1-1-indenyl with D3-methyl. In conclusion, the major source of paramount 133 and 134 peaks may not be mainly from bimolecular reactions, but they should originate from different indenyl precursors.

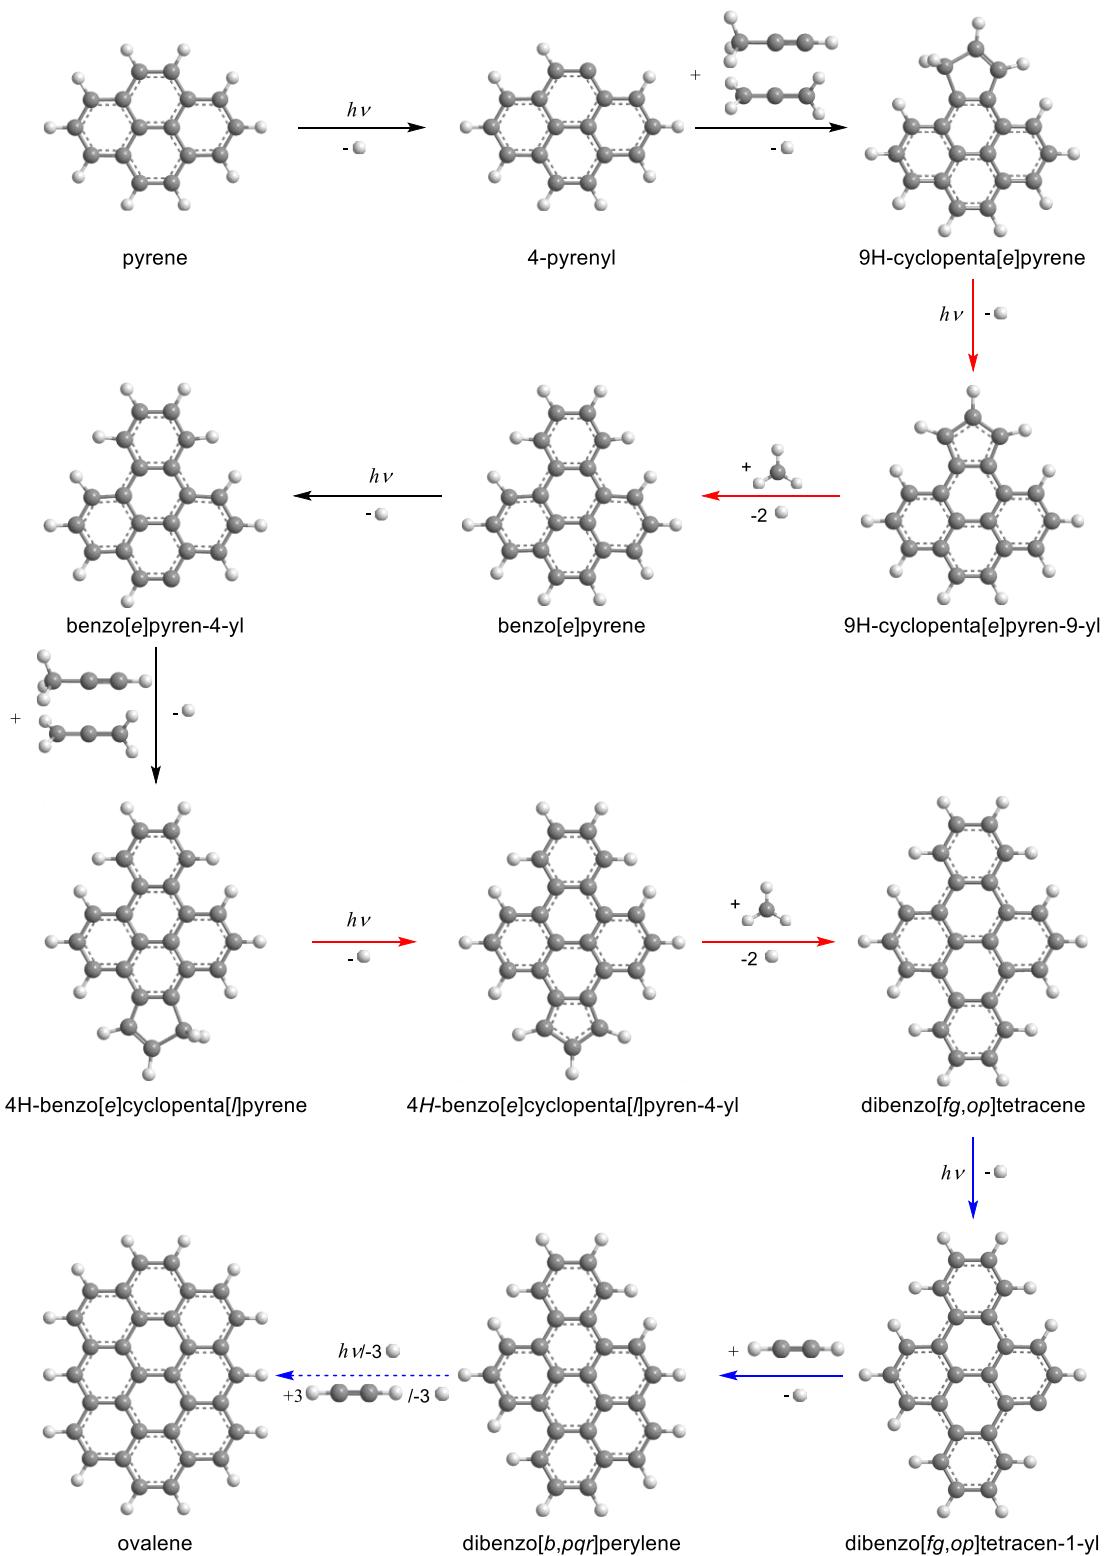

Signal of $m/z = 146$ to 149 (Supplementary Figs. 7(k)-(n)) is attributed to D4-, D5- and D6-1-methylnaphthalenes and their ^{13}C counterparts ($C_{11}H_6D_4$, $m/z = 146$, Supplementary Fig. 7(k); $^{13}CC_{10}H_6D_4/C_{11}H_5D_5$, $m/z = 147$, Supplementary Fig. 7(l); $^{13}CC_{10}H_5D_5/C_{11}H_4D_6$, $m/z = 148$, Supplementary Fig. 7(m); $^{13}CC_{10}H_4D_6$, $m/z = 149$, Supplementary Fig. 7(n)). These deuterated methylnaphthalenes are proposed to be generated via the corresponding deuterated naphthalene with D3-methyl followed by H- or D-loss.³

Analogous to the 1-indenyl – methyl system, signal at m/z = 150 to 152 (Supplementary Figs. 7(o)-(q)) is attributed to products via the reaction of D3-, D4-, D5-methylindenanes ($C_{10}H_7D_3$, m/z = 133; $C_{10}H_6D_4$, m/z = 134; $C_{10}H_5D_5$, m/z = 135) and D3-methyl after H- or D-loss. Due to the lack of reference PIE data, species at m/z = 150 to 152 remain unidentified. With deuteration in different carbon positions in the 1-indenyl radical, subsequent reactions lead to a variety of deuterated products.

Please note that we cannot differentiate between ^{13}C -D3-methylindene and D4-methylindene. Based on the isotope ratio and the experimental findings, this would suggest that we are making copious amounts of D4-methylindene, which means that a deuterium atom is also substituting a hydrogen atom in the ring as described in Supplementary Figure 9 in the Supplementary Material. Here, the reaction of indenyl plus deuterium forming D1-indene followed by decomposition to D1-indenyl plus atomic hydrogen is exoergic because the C-H bond is weaker than the C-D bond due to the effect of zero-point vibrational energy. This process is followed by the reaction of D1-indenyl plus D3-methyl to give D4-methylindene (m/z = 134).

Supplementary Figure 10: Schematic hydrogen abstraction - methylacetylene/allene addition pathways leading to distinct cyclopentanaphthalenes isomers. Successive radical-radical mechanisms could form anthracene and phenanthrene. This pathway is presented schematically for interstellar environments (photon induced hydrogen loss); in combustion systems, the hydrogen atom can be lost via hydrogen abstraction by hydrogen atoms ubiquitous in flames.

Supplementary Figure 11: Schematic representation of the complementary nature of the novel radical-radical (red) and the hydrogen abstraction-acetylene addition (HACA) mechanisms (blue) leading to planar PAHs. This pathway is presented schematically for extraterrestrial environments (photon induced hydrogen loss); in combustion systems, the hydrogen atom can be abstracted by a hydrogen atom ubiquitous in flames.

Pyrene ($C_{16}H_{10}$) can be photolyzed by interstellar UV photons leading to the formation of the 4-pyrenyl radical ($C_{16}H_9\cdot$), which reacts with allene/methylacetylene to yield 9H-cyclopenta(*e*)pyrene ($C_{19}H_{12}$). The latter can also be photolyzed yielding 9H-cyclopenta(*e*)pyren-9-yl ($C_{19}H_{11}\cdot$), which then can react with the methyl radical leading to benzo[*e*]pyrene ($C_{20}H_{12}$). Similarly, benzo[*e*]pyrene is proposed to follow the sequence of photon induced hydrogen loss to benzo[*e*]pyren-4-yl, allene/methylacetylene addition to 4H-benzo[*e*]cyclopenta[*I*]pyrene, photon induced hydrogen loss to 4H-benzo[*e*]cyclopenta[*I*]pyren-4-yl, and finally the reaction with a methyl radical generating dibenzo[*fg,op*]tetracene ($C_{24}H_{14}$). Dibenzo[*fg,op*]tetracene undergoes the successive steps of photon induced hydrogen loss and hydrogen abstraction-acetylene addition (HACA) mechanisms leading eventually to the formation of a more complex two-dimension PAH ovalene ($C_{32}H_{14}$).

Supplementary Note 2: Cartesian coordinates, vibrational frequencies, relative energies and hindered rotor potentials for various species in the indenyl + CH₃ reaction in the form of MESS input file.
