Suppmentary Methods - DNA Extraction and Genotyping Protocol

DNA was extracted by isopropanol precipitation in 96-well plates. Half a fly thorax was added to a well containing 4ul Proteinase K (10 mg.ml-1) and 100ul DIGSOL (25mM NaCl, 1mM EDTA, 10mM Tris-Cl pH 8.2), mechanically lysed, and incubated overnight at 55C. The following day, 35ul of 4M ammonium acetate was added and plates were left on ice for 5 minutes before being centrifuged at 4500RPM at 4C for 40 minutes. 80ul of supernatant was then aspirated into a new 96-well plate containing 80ul of isopropanol. The precipitate was discarded. Samples were then centrifuged again at 4500RPM and 4C for 40 minutes to precipitate the DNA. The supernatant was then discarded, 100ul 70% ethanol was added, and samples were spun again at 4500RPM and 4C for 20 minutes. The supernatant was once again discarded and plates were left to air-dry for 45 minutes at room temperature. Finally, 30ul of Low TE (1mM Tris-HCL pH8, 0.1mM EDTA) was added to elute the DNA. DNA was PCR-amplified in 96-well plates, with each well containing 1ul of dried DNA, 1ul of primer mix (consisting of the forward and reverse primers of comp162710 at a concentration of 0.2uM) and 1ul of QIAGEN Multiplex PCR Masternix (Qiagen). The length of amplified fragments was determined by gel electrophoresis. A 3% agarose gel was made using 3g of molecular grade agarose, 100ml of 0.5x TBE buffer (45mM Tris (pH 7.6), 45mM boric acid, 1mM EDTA), and 4ul ethidium bromide. PCR products were diluted with 3ul ultrapure water and 2ul of gel loading dye was added. 4ul of this mixture was loaded into each well and assessed for size against a ladder made from the PCR-amplified DNA of multiple heterozygous drive females. comp162710 is an indel marker with small alleles (201bp) indicating the presence of the drive chromosome and large alleles (286bp) indicating the presence of the standard chromosome (GS Wilkinson, personal communication; Meade et al. 2019).

Model outputs

Supplementary table S1

The effect of food condition on egg-to-adult viability in males:

Supplementary table S3

As food condition did not affect egg-to-adult viability, condition was removed from subsequent analysis. Below are the full model results from linear mixed effect models examining the effect of genotype on egg-to-adult viability.

The effect of genotype on egg-to-adult viability in males:

| | Estimate | Std. Error | df | t value | $\Pr(> t)$ |
|---------------------------|------------------------|------------------------|----------|-----------------------|-------------|
| (Intercept) ConstructV | 0.4167260 0.1375502 | 0.0390008 0.0401625 | 16.94126 | 10.685053 3 424845 | 0.0000000 |

| | | | | | | | | | |
| | Su | ım Sq | Me | an Sq | Num | DF | DenDF | F value | $\Pr(>F)$ |
| Genotype | 0.82 | 39569 | 0.41 | 19784 | | 2 | 120 | 4.759265 | 0.0102556 |

Supplementary table S5

The viability of both male genotypes was estimated directly from the model output of the more simplified linear model below.

m1 <- lm(data=Male_Survival, formula = W ~ Genotype)</pre>

| | Estimate | Std. Error | t value | $\Pr(> t)$ |
|---------------------------|--------------------------|--------------------------|-------------------------|------------------------|
| (Intercept) GenotypeXY | $0.4063265 \\ 0.1375502$ | $0.0307031 \\ 0.0434207$ | $13.234068 \\ 3.167849$ | 0.0000000 0.0018358 |

Here the X^{SR}/Y genotype is used as the comparison, so its egg-to-adult viability is the model intercept term, 0.40633. The viability of X^{ST}/Y (labelled as simply GenotypeXY in the model), is calculated by adding the intercept term and the effect term together: 0.40633 + 0.13755 = 0.54388.

Supplementary table S6

The viability of each female genotype was estimated in the same way as above:

m1 <- lm(data=Female_Survival, formula = W ~ Genotype)</pre>

| | Estimate | Std. Error | t value | $\Pr(> t)$ |
|----------------------------|--------------------------|--------------------------|------------------------------|--------------------------|
| (Intercept) GenotypeSRX | $0.4649979 \\ 0.0841424$ | $0.0395727 \\ 0.0559642$ | $\frac{11.750485}{1.503505}$ | $0.0000000 \\ 0.1344614$ |
| GenotypeXX | 0.1643466 | 0.0559642 | 2.936639 | 0.0037515 |

Supplementary table S7

To determine if the three female genotypes had significantly different viabilities, we used a Tukey's post-hoc comparison test:

| | diff | lwr | upr | p adj |
|---------------------|---|-------------------------|---|---|
| SRX-SRSR XX-SRSR | $\begin{array}{c} 0.0841424 \\ 0.1643466 \end{array}$ | -0.0481157 0.0320885 | $\begin{array}{c} 0.2164006 \\ 0.2966048 \end{array}$ | $\begin{array}{c} 0.2916928 \\ 0.0104345 \end{array}$ |
| XX-SRX | 0.0802042 | -0.0520539 | 0.2124623 | 0.3260922 |

Fertility trial - Supplementary table S8

Below are the results of a trial designed to test the fertility of eggs laid by X^{SR}/X^{ST} females crossed to X^{SR}/Y (Cross A) and X^{ST}/Y (Cross B) males. One day old eggs were collected and counted, then allowed to develop for a further five days. After five days of development, the vast majority of fertilised eggs have hatched, and the remainder of show clear signs of development (eg segmental striations, darker colouration, development of mouthparts, etc.). At this time, the number of hatched/fertilised eggs were counted, along with the number of unfertilised eggs. In this trial, eggs were not inspected for signs of development before they were collected, and yet fertility remains high. There is no obvious difference in the fertility of Cross A and Cross B.
