

Fig. S3

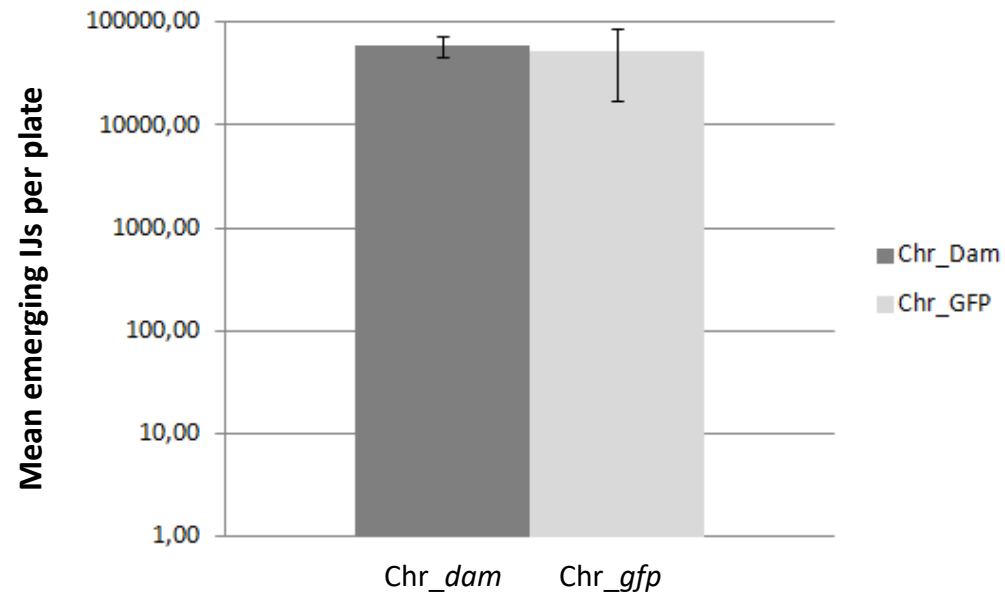

Figure S3. Emerging IJs from in vitro symbiosis association.

For each *P. luminescens* strain, three independent cultures were used to establish symbiosis with *H. bacteriophora*. Emerging IJs were then counted and the mean of three biological replicates is represented for Chr_dam strain (dark grey) and Chr_gfp (light grey) (see Materials & Methods section for details). The level of emergence between the 2 strains was not significantly different (Wilcoxon, $p=0.63$).
