Primer sets were tested for matches to sequences in the SILVA database (v.132) using TestPrime with the parameters (maximum number of mismatches of three bases and length of 0-mismatch at the 3' end of three bases). TestPrime computes coverages for each taxonomic group by running *in silico* PCR on the SILVA database via sorting database sequences into "match", "mismatch" and "nodata (sequences not covering the primer match position)". The frequencies of "match" sequences among "match" and "mismatch" sequences are shown as percentages with the sequence numbers in parentheses.

¹ Only 17 bases from the 3' was used for the primer EukBr because many sequences in the SILVA database lacks the corresponding 5' region.

² Target variable regions and amplicon sizes based on the *S. cerevisiae* rRNA gene (NC_001144) are shown below the primer names.

Table S3. Primer sets targeting the 18S or 28S rRNA gene and their coverages in 13 taxonomic groups under a mild TestPrime parameter set (maximum number of mismatches of five bases and length of 0-mismatch at the 3' end of three bases)

Primer sets were tested for matches to sequences in the SILVA database (v.132) using TestPrime with the parameters (maximum number of mismatches of five bases and length of 0-mismatch at the 3' end of three bases). TestPrime computes coverages for each taxonomic group by running *in silico* PCR on the SILVA database via sorting database sequences into "match", "mismatch" and "nodata (sequences not covering the primer match position)". The frequencies of "match" sequences among "match" and "mismatch" sequences are shown as percentages with the sequence numbers in parentheses.

¹ Only 17 bases from the 3' was used for the primer EukBr because many sequences in the SILVA database lacks the corresponding 5' region.

² Target variable regions and amplicon sizes based on the *S. cerevisiae* rRNA gene (NC_001144) are shown below the primer names.

³ These primer sets could not be evaluated by the TestPrime.

Primer sets were tested for matches to sequences in the SILVA database (v.132) using TestPrime under parameters (maximum number of mismatches of 4 bases, and length of 0-mismatch at 3' end of 3 bases). TestPrime computes coverages for each taxonomic group by running an in silico PCR on the SILVA database by sorting database sequences into “match”, “mismatch” and “nodata (sequences not covering the primer match position)”. The frequencies of “match” sequences out of “match” or “mismatch” sequences are shown in percentages.

¹ Target variable regions and amplicon sizes based on *S. cerevisiae* rRNA gene (NC_001144) were shown below primer names.

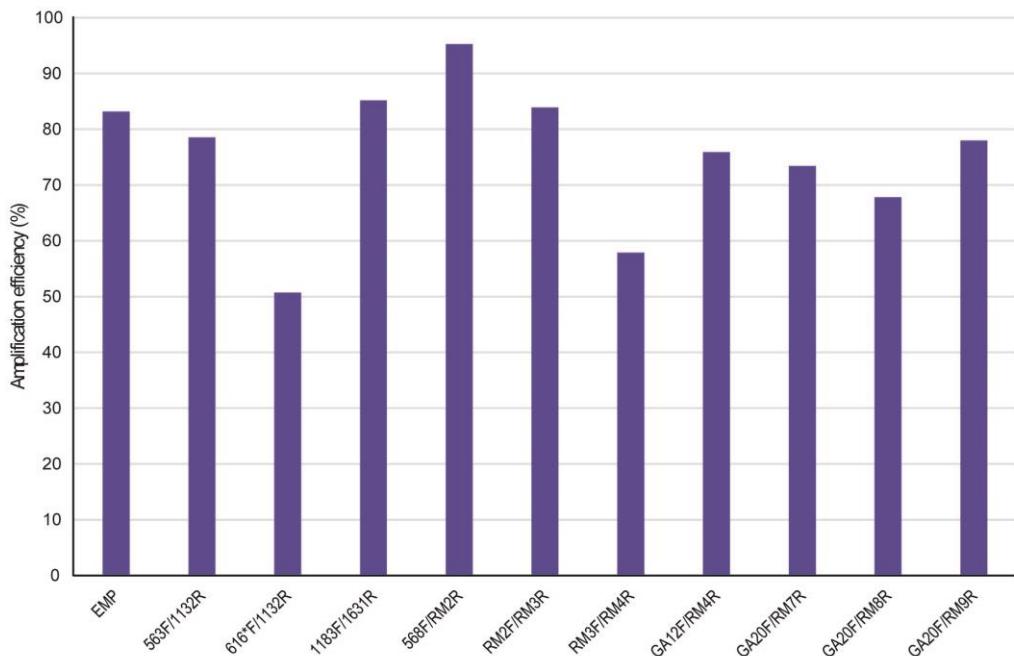

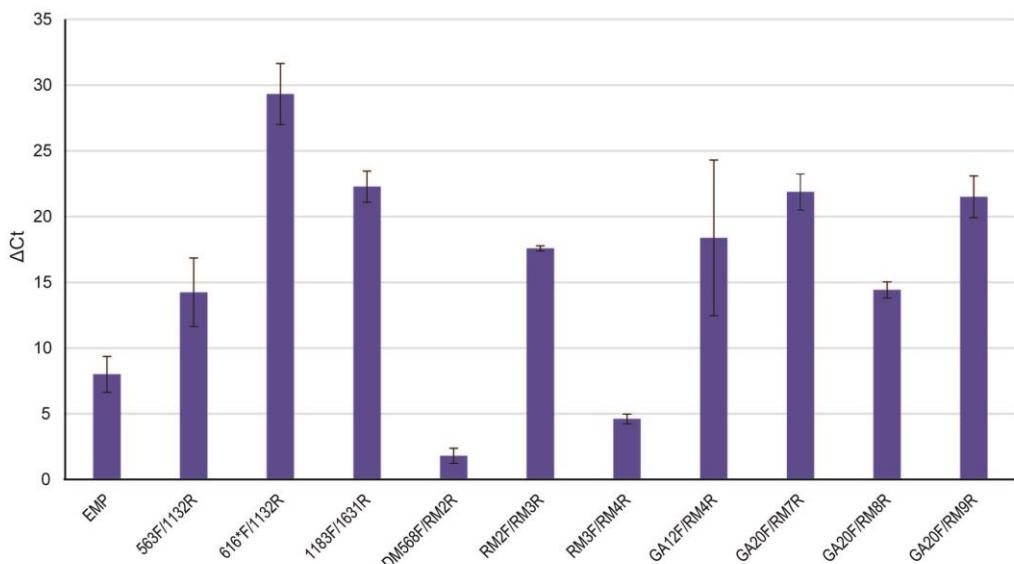

A**B**

Fig. S1. PCR amplification efficiency and bacterial amplification of 18S and 28S primer sets. (A) PCR efficiencies were calculated for each primer set targeting 18S or 28S rRNA genes using *C. elegans* genomic DNA as templates. (B) Differences of Ct (Cycle threshold) values between the two templates (Ct with 0.1 ng bacterial DNA minus Ct with 0.1 ng *C. elegans* genomic DNA) were shown for each primer set. Error bars represent S.E. from triplicate data.
