Abstract

Objective: Telemedicine has been promoted as an economical and effective way to enhance patient care but the acceptability among patients is poorly understood. This study aimed to explore the experiences and perspective of type 2 diabetes mellitus patients who use telemedicine to manage their condition.

Design: We conducted an in-depth interviews and focus group with participants who used telemedicine. Questions included participants' perception of program use, satisfaction as well as engagement with program. All interviews and focus groups were audio-recorded and transcribed verbatim. The data were analyzed using a thematic approach.

Participants and setting: All type 2 diabetes patients who had participated in a randomized controlled study examining the use of telemedicine for the management of diabetes.

Results: Twelve focus groups and two in-depth interview with a total of 48 adults were conducted and four themes emerged from the analysis. (1) The younger generation was more receptive to telemedicine. (2) Using telemedicine was a convenient solution to care for their disease. (3) Sharing of personal health status with family members kept patients accountable for their health. (4) Some participants expressed concerned about their privacy infringement, presence of malware and costs.

Conclusion: Despite the potential positive benefits of using telemedicine for diabetes care, several barriers could inhibit the sustained and effective use of this technology. As such, collaboration between educators, health care providers,

1
2
3 telecommunication service providers and patients is required to stimulate
4
5 telemedicine adoption and use.

6 7 **Strengths and limitations of this study**

- 11 • This study focused on the acceptability and perception towards using
12 technology for the management of type 2 diabetes
13
- 14 • We captured the views, experiences, as well as barriers and facilitators to
15 using telemedicine of patients rather than healthcare providers, as these tend
16 to be frequently overlooked
17
- 18 • The study was conducted in an urban setting in Malaysia and its applicability
19 and transferability to other population remains unknown.

Introduction

Diabetes is a major health concern worldwide, and according to a recent report by the International Diabetes Federation, the global prevalence of diabetes has increased from 415 million in 2015 to 425 million in 2017¹. The prevalence varies considerably between different regions, but the epicenter of the diabetes crisis is currently located in the Western Pacific and South-East Asia region, with 159 million and 82 million individuals with diabetes respectively. In many individuals with diabetes, self-monitoring of blood glucose (SMBG) is considered a key component of treatment, and widely recommended by clinical practice guidelines irrespective of treatment strategy²⁻⁴. SMBG is often used as an early warning sign for detecting hypoglycemia, for improving the recognition of severe hyperglycemia, to encourage physical activities as well as improve diet control. These data are also often used by the treating physician to facilitate an individualized treatment regimen.

Despite these potential benefits, there is controversy on the efficacy of SMBG especially in non-insulin dependent type 2 diabetes due to its cost, uncertainty on frequency of testing as well as impact on patients' general health and well-being. Studies of enhanced SMBG which involved engagement of patients and/or clinicians to interpret the SMBG values found that larger HbA1c reduction compared to only regular SMBG which did not involve any active participation from any parties³⁻⁷.

The application of telemedicine in diabetes management has been suggested as an innovative solution to improve diabetes care⁸⁻¹⁰. Increasingly, telemedicine is being viewed as a promising technology in assisting patients to manage their diabetes^{9 11}¹². The use of telemedicine is promising in diabetes management, as it produces

1
2
3 accurate and reliable data, empowers patients, improves glycemic control and
4 influences their attitude and behaviors, potentially leading to a better quality of life¹¹⁻
5
6
7 ¹³. Additionally, telemedicine has the potential to reduce the barrier to adherence of
8
9 self-management through real-time data transfer between patient and provider, the
10
11 review glucose measurement trends, and a reduction opportunity costs. Some
12
13 potential telemedicine applications and technologies that have been examined to
14
15 date include mobile phones, texting, emails, e-health portals, videoconferencing as
16
17 well as devices¹⁴.
18
19
20
21

22 However, implementation of a telemedicine service in conventional care is a complex
23
24 process. Studies have shown that while telemedicine can expand the boundaries of
25
26 care to a larger population, there is heavy resistance to change, especially among
27
28 patients^{15 16}. Nevertheless, one of the major limitation of existing literature is the lack
29
30 of studies which has examined the perspective of patients from a low-middle income
31
32 country. Therefore, the goal of this study was to explore patients' views and
33
34 experiences of telemedicine for diabetes management in Malaysia.

Materials and Methods

Study design

This qualitative study used a purposive sampling to select participants who had been part of a larger multicenter randomized controlled study, Intervention for Diabetes with Education, Advancement and Support (IDEAS) reported elsewhere (Box 1)¹⁷. Participants were approached for the qualitative study when they agreed to participate in the study, but participation for the in-depth interview was optional. The clinics in the study were drawn from a nationally representative list of clinics in Klang Valley, Malaysia.

Participants and Procedure

Participants for this qualitative study were patients who received care in one of the eleven clinics which provided diabetes care. Selection criteria for participants included: (1) diagnosed with type 2 diabetes, (2) received a web-enabled glucometer, (3) provided written informed consent and (4) agreed to be contacted by phone or in person for any clarification after the interview. All potentially eligible participants were contacted by telephone and invited to participate in the study. All focus groups interviews were conducted at the health clinic during the follow-up to accommodate participants schedule as much as possible. If participants were not able to attend a focus group session, an individual in-depth interview at their own home was conducted instead.

A set of open-ended questions was employed as the interview guide to capture the experiences of patients in using telemedicine. Interviews were conducted in either in

1
2
3 the Malay or English language, led by the first author (JYL). Interviews continued
4
5 until the researcher, in discussion with the wider research team considered data
6
7 saturation or no new themes or codes could be identified
8
9

11 **Ethics**

12
13 The Monash University Research Ethics Committee (CF14/1977 – 2014001016 &
14
15 CF15/1073 - 2015000502) and the National Medical Research Register (NMRR-14-
16
17 177-19466 & NMRR-14-1368-22943) approved this study. This study was registered
18
19 with ClinicalTrials.gov under the registration NCT0246680.
20
21
22
23

24 **Patient and public involvement**

25
26 The study was designed to understand the patients' views, perception and
27
28 experience of using telemedicine for type 2 diabetes management. However,
29
30 patients were not included in the design of the study, interview questions or conduct
31
32 of study. Patients who participated in this qualitative study did so anonymously, and
33
34 thus we could not disseminate the results to study participants.
35
36
37
38
39

40 **Data Analysis**

41
42 All sessions were audio recorded and fully transcribed verbatim. These transcripts
43
44 were read several times to familiarize with the data. The data were subsequently
45
46 analyzed using thematic analysis, allowing the researchers who worked in teams to
47
48 identify, analyze and report the patterns or themes within a set of data¹⁸. All themes
49
50 were derived inductively from the data where codes and theme development were
51
52 directed by the content of the transcribed data. All coding was checked and

iteratively refined using paired analysis of transcripts by two researchers (JYL and SWHL).

For peer review only

Results

A total of 48 participants were interviewed in the 12 focus group (average 3-4 participants per group) and 2 interview sessions. The participants were mostly females (56.3%), with a mean age of 51.9 years, and a mean duration of diabetes of 5.6 years (Table 1). Four core themes emerged from our interviews: (1) Age is a key factor (2) Its time saving, (3) My family and my life and (4) User experience and data security.

Theme 1 – Age is a key factor

Overall, we noted that there were two distinct groups of participants with regards to their preference on how to record their blood glucose reading. In general, older participants (those aged 50 years and above) preferred to record their glucose readings manually, using pen and paper. They found that using a telemonitoring device required a lot of technical know-how and that it was a challenging and complex process. As explained by the participants:

I manually record. I do not understand telephone especially opening. To me manual is easier. [Patient 4, 59/F].

But I am an old person I like it to be written. I'm old I need to write down. Anyway as long as someone shows me how to do it I can do it. Of course it's easier because you bring your hand phone everywhere you go. [Patient 5, 57/F]

1
2
3
4
5
6
7
8
9 However, participants were generally enthusiastic as they saw the potential benefits
10 of telemedicine. They expressed the desire and need to have more training and
11 assistance, especially when they had not used the device for some time, since they
12 would have forgotten how it functions and to use.
13
14
15
16
17
18
19

20 For me it's not difficult just need to teach that's all. See the learning condition
21 first maybe need two or three times. I'm over fifty [years old] so first time will
22 be a problemneed to teach a few times before I understand. First time
23 might be difficult to understand. [Patient 7, 56/M]
24
25
26
27
28
29
30
31
32

33 These participants felt that the use of telemedicine was more suitable for the
34 younger diabetes patients who were more technology savvy. As one explained it,
35 "Maybe for the young ones la. Technology for youngsters is more suitable since they
36 like to sit at home and like the thing called Internet." Some participants also
37 expressed their preference to meet their health care providers in person and
38 reported that travelling to the clinic was not an onerous task.
39
40
41
42
43
44
45
46
47

48 I don't mind coming to the clinic and have a chat with the doctor. We discuss
49 and sometimes we can ask questions and doctors can show it physically.
50 For me to use the Internet is difficult to learn my children are not here.
51
52
53
54 [Patient 6, 60/M, Malay].
55
56
57
58
59
60

1
2
3
4
5
6
7 Conversely, younger participants were more inclined to learn and use new
8 technologies if sufficient training and guidance were given. Additionally, they were
9 optimistic about using telemedicine to manage their conditions, as they knew the
10 various benefits that technology would provide, including data tracking ability and
11 convenience.
12
13
14
15
16
17
18
19
20

21 Digital way. Everyday you can see it in your digital way in the
22 software so no need to record like manual. Sometime even you record
23 manual the paper wherever missing. Digital you have a backup.
24
25
26

27 [Patient 8, 35/F]
28
29
30

31
32 I like this because you can transfer directly to your phone. It's useful to
33 me as an indication. I prefer that I can use it to check my medicine
34 effect my glucose. I think that this is the best tools because you can
35 monitor by the Internet everywhere you go. [Patient 9, 44/M]
36
37
38
39
40

41
42 It's even more convenient since we do not have the time to come and
43 sometimes some people do not have transport. [Patient 10, 44/F]
44
45
46
47
48
49
50

51 **Theme 2 – Its time saving**

52
53 Participants expressed that the use of a mobile phone which is connected to a
54 glucometer is a convenient alternative for the management of diabetes. Participants
55
56
57
58
59
60

1
2
3 viewed that it is a more convenient option in the event of time constraints and a lack
4 of transportation to the clinic. Participants also revealed how having a telemonitoring
5 device encouraged them to monitor their glucose levels regularly compared to the
6 quarterly check-ups at the clinic. As expressed by one participant “It’s good to use
7 especially over the Internet. It’s so much easier we do not have to come to the clinic
8 and can stay at home (Patient 12, 60/M)”.

19 20 **Theme 3 – My family and my life**

21
22 Our analysis showed that there was some conflicting perspective when it comes to
23 data sharing. Several participants expressed that they were willing to share their
24 monitoring results with family members, as they felt that the family member would
25 keep them accountable to their diabetes management, which was a significant
26 motivation for them to meet their daily goals.

27
28
29 The use of this what you call it [web-telemonitor]..... my health is
30 good especially when family members want to monitor your sugar
31 control can monitor as well. [Patient 11, 54/F]

32
33
34
35
36
37
38
39
40
41
42
43
44 It’s a good part because of this you can do it at home. If at the clinic you
45 get pricked nobody knows but when you do it at home you children will
46 be informed as well. [Patient 5, 57/F]

1
2
3 Conversely, some participants expressed concerned that the sharing of medical
4 information with their family members might infringe on their personal space and
5 potentially cause conflicts between members of the family.
6
7
8
9

10
11 That thing is okay but what I am afraid of is sometimes conflicts because it
12 feels like you are being monitored by others. But it is beneficial at least there
13 is somebody remind you. [Patient 1, 45/M]
14
15
16
17
18
19
20
21

22 **Theme 4 – User experience and data security**

23
24
25

26 Participants in this study emphasized the importance of having a user-friendly
27 technology. Most participants in this study reported minor technical difficulties related
28 to internet connectivity and availability during the study, which limited their ability to
29 utilize the telemonitoring device effectively. Additionally, participants expressed
30 concern they had about the presence of malware in telemonitoring devices that could
31 compromise their personal information.
32
33
34
35
36
37
38
39
40
41
42
43

44 Problem with the Internet. Occasionally we can receive the reading
45 occasionally are unable too. Very inconvenient. [Patient 11, 54/F].
46
47
48
49

50 I think depend on the situation where you live in a village very difficult now
51 also because certain villages you don't have (Internet) line so you still need
52 have the manual. [Patient 8, 35/F]
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7 As explained by one participant, having a robust system which is user-friendly, and
8 has good support is essential to ensure that the implementation of telemedicine is
9 successful “Okay (lah) but what happens when there is a virus? It is a problem for
10 one week my handphone hang. After one week it hang that is a problem” (Patient 13,
11 54/F).
12
13
14
15
16

17 Another aspect which participants were worried of was the costs involved compared
18 to conventional care and that telemonitoring would only be suitable for affluent
19 patients.
20
21
22
23
24
25

26 All this (telemedicine) is for people who are wealthy. Of course this is a good
27 system. [Patient 14, 63/M]
28
29
30
31
32

33 Some participants also found that meeting health care providers personally was a
34 faster method to solve their queries as they felt that health care practitioners would
35 be able to explain their clinical measures in a more concise manner. As explained by
36 one participant “Face-to face (consultation) is more important (as) its better. (With)
37 face-to face (consultation), information is clearer, more satisfying and friendly
38 (Patient 2, 67F).”

Discussion

In our study, we present the conditions for the success of a telemonitoring health device for managing type 2 diabetes, from patients' perspective. We identified a set of distinctive but interrelated condition which is central to the success of such programs. Firstly, participants' demographics played a crucial factor in ensuring the acceptability of telemedicine. We noted that younger participants between ages of 29-50 years old preferred using a web-based glucometer compared to older participants who preferred recording their results manually. Such outcome is not surprising as young individuals who grew up in this digital era are usually more technologically savvy compared to their older counterparts^{19 20}. Participants cited various reasons for being unable to use a web-based glucometer, among them were the lack of Internet connection especially in the rural areas. Indeed, concerns about the stability of Internet connection was the biggest barrier in using telemedicine in diabetes care in this study. The need for a simple, user friendly technology was also consistently highlighted, to encourage acceptability among participants to use a remote telemonitoring system^{8 21 22}.

As telemedicine technology is improving continuously, participants expressed enthusiasm on the potential added value of telemedicine. Most participants were willing to incorporate technology as part of their diabetes management, but expressed the need to have sufficient training and on-going support, especially when they encountered issues such as equipment limitations. Our study also identified the potential benefits which fueled participants' enthusiasm towards telemedicine. These include receiving alerts, being able to respond to SMBG readings with advice from a

1
2
3 health care professional; as well as reducing opportunity cost incurred when using
4 telemedicine²³. Our study also offers an additional perspective and insight into the
5 importance of patient-provider relationship. Our results support previous research
6 which indicated that personal interaction with a health care practitioner was an
7 important aspect to support type 2 diabetes patients, especially when it involves
8 SMBG²⁴. This view was also expressed by most participants in the present study,
9 and also that a lack of emotional support especially when communicating through
10 remote telemonitoring resulted in participants dropping out of the study⁹.

11
12
13
14
15
16
17
18
19
20
21
22 Our study also noted that not all participant perceive enhanced SMBG as a positive
23 tool to help achieve good glycemetic control. Some participants in this study expressed
24 reservation on the feedback and monitoring feature, which they felt intruded into their
25 personal space. They also expressed some tension between achieving good
26 glycemetic control and quality of life, especially with the involvement of health care
27 providers and family members whom they felt were acting as a “police”. As a results,
28 some of these patients opted not to take part in the study, for fear that this could
29 further amplify the tension and strain the relationship, an outcome which they
30 definitely did not want. By exploring the insights of patients, we illustrate how family
31 values and technology literacy could influence participants’ opinion on
32 telemonitoring. Our study was also culturally specific to an Asian context and thus,
33 we could gain an in-depth understanding and broader views of participants’
34 behaviors when managing diabetes.

35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51
52 There were some limitations to our study. Firstly, although we had included a diverse
53 sample of participants and reached thematic saturation in our interviews, these
54
55
56
57
58
59
60

1
2
3 participants are only limited to one geographical location in Malaysia. Participants
4
5 were from suburban districts in Selangor where connectivity and technology literacy
6
7 were moderate. Future studies should include patients from both urban as well as
8
9 rural location and those with high technology literacy, as this could potentially
10
11 influence the uptake and acceptability of telemedicine. While published literature
12
13 suggest that the trends are likely generalizable to other regions in Malaysia, the
14
15 context may differ among other countries and settings. The views expressed here
16
17 are solely from a patients' point and does not represent the views of health care
18
19 providers or policy makers. Finally, our sample size was not large enough to draw
20
21 definitive conclusion regarding differences in provider practices, patient knowledge
22
23 as well as attitudes from different clinic sites.

31 **Implications for practice**

32
33 The continual improvements in technology will facilitate the use of telemedicine in
34
35 future. The largest implication will be its ability to reduce logistical barriers as well as
36
37 saves time. However, it is important to also consider the economic standing of
38
39 patients living in rural areas, who may have limited internet connectivity. As such,
40
41 health care professionals and policy makers need to consider these aspects prior to
42
43 introducing any telemedicine technology for their patients to ensure that patients'
44
45 expectations are met.
46
47
48
49

50 Another theme that emerged from this interview was the need to invest in capacity
51
52 building especially in human resources. Specifically, the creation of training
53
54 programs for both public as well as health workers are particularly important,

especially among the non-IT savvy groups. In addition, there is also a need to simultaneously create a policy for the integration of telemedicine into the health service system and aligning it to correspond with local and national health strategies.

For peer review only

Conclusion

In conclusion, findings from this study indicate that the implementation of telemonitoring requires strategic planning with inputs from various stakeholders including, educators, health care providers, telco service providers and patients. These need to take into consideration the patient's personal and contextual factors, which could have a positive or negative effect. As such, health care providers need to discuss patients' perspective to ensure the optimal use of telemedicine to improve patients' clinical parameters and quality of life.

Acknowledgements

The authors would like to thank all participants and health providers who contributed their time to share their perspectives with us.

Funding source

This study was supported by the e-Science fund from the Ministry of Science, Technology and Innovation, Malaysia [03-02-10-SF0238 (MOSTI)], Telemedicine Cluster, Tropical Medicine and Biology platform, Monash University Malaysia (52140757-314-00) and SEGi University Research Fund (SEGi/2013/SKK/04/1).

Box 1: IDEAS study

The Intervention for Diabetes with Education, Advancement and Support (IDEAS) study is a cluster randomized controlled study to evaluate the use of telemedicine to improve diabetes care. Participants in the telemedicine group were instructed to measure their blood glucose at least twice weekly (one fasting and one non-fasting) or more frequent as recommended by physician. These blood glucose readings will be transmitted via a Bluetooth technology to the participants' mobile phone to a remote secure server. Participants and their physicians were able to access the records on the server. Advice on lifestyle modification, any potential changes in medication, who and how to contact their healthcare providers were also given monthly during the study. A researcher also checked participants' results weekly and initiate intervention if needed (e.g. medication changes, counselling) with the consent of the attending physician.

Abstract

Objective: Telemedicine has been promoted as an economical and effective way to enhance patient care but its acceptability among patients in low and middle income countries are still poorly understood. This study aimed to explore the experiences and perspective of people with type 2 diabetes mellitus patients who use telemedicine to manage their condition.

Design: We conducted in-depth and focus group interviews with participants who used telemedicine. Questions included participants' perception of program use, satisfaction as well as engagement with program. All interviews and focus groups were audio-recorded and transcribed verbatim. The data were analyzed using a thematic approach.

Participants and setting: All people with type 2 diabetes who participated in a randomized controlled study examining the use of telemedicine for the management of diabetes.

Results: Twelve focus groups and two in-depth interviews with 48 adults were conducted and four themes emerged from the analysis. (1) Generational difference (2) Independence and convenience, (3) Sharing health data and privacy; and (4) Concerns and challenges. The main barriers to using telemedicine were related to the user friendliness of the devices as well as internet connectivity. Cost was also another significant concern raised by participants. However, participants generally were positive about the benefits of telemedicine, including reduction in clinic visits, ability to provide real time data and disease monitoring.

Conclusion: Despite the potential positive benefits of using telemedicine for diabetes care, several barriers could inhibit the sustained and effective use of this technology.

1
2
3 As such, collaboration between educators, health care providers, telecommunication
4 service providers and patients is required to stimulate telemedicine adoption and use.

Strengths and limitations of this study

- Article followed the Standards for reporting qualitative Research (SRQR) recommendations on reporting
- Focus group discussion allowed the exchange of opinions about telemedicine, leading to richer information
- View and experiences of using telemedicine from patients were captured rather than that of healthcare providers
- The study was conducted in an urban setting in Malaysia and its applicability and transferability to other population remains unknown.

Introduction

Diabetes is a major health concern worldwide, and according to a recent report by the International Diabetes Federation, the global prevalence of diabetes will increase from 415 million in 2015 to 642 million in 2040.¹ The prevalence varies considerably between different regions, but the epicenter of the diabetes crisis is currently located in the Western Pacific and South-East Asia region, with 159 million and 82 million individuals with diabetes respectively.² In many individuals with diabetes, self-monitoring of blood glucose (SMBG) is considered a key component of treatment, and widely recommended by clinical practice guidelines irrespective of treatment strategy.³⁻⁵ SMBG is often used as an early warning sign for detecting hypoglycaemia, for improving the recognition of severe hyperglycaemia, to encourage physical activities as well as improve diet control. These data are also often used by the treating physician to facilitate an individualized treatment regimen.

Despite these potential benefits, there is controversy on the efficacy of SMBG especially in non-insulin dependent type 2 diabetes due to its cost, uncertainty on frequency of testing as well as impact on patients' general health and well-being.⁶⁻⁸ Studies have shown that the use of enhanced SMBG (where there are high levels of engagement between patients and clinicians to interpret the SMBG values) resulted in larger HbA1c reduction compared to regular SMBG.^{4 9-11}

The application of telemedicine, or technology to deliver various aspects of health information, prevention, monitoring and medical care in diabetes management has been suggested as an innovative solution to improve diabetes care.¹²⁻¹⁴ Increasingly,

1
2
3 telemedicine is being viewed as a promising technology in assisting patients to
4 manage their diabetes,^{13 15 16} as it produces accurate and reliable data¹⁷, empowers
5 patients¹², improves glycaemic control and influences their attitude and behaviours¹⁶

telemedicine is being viewed as a promising technology in assisting patients to manage their diabetes,^{13 15 16} as it produces accurate and reliable data¹⁷, empowers patients¹², improves glycaemic control and influences their attitude and behaviours¹⁶, potentially leading to a better quality of life.¹⁹ Additionally, telemedicine has the potential to reduce the barrier to adherence of self-management through real-time data transfer between patient and provider, the review of blood glucose measurement trends, and a reduction in opportunity costs. These telemedicine services can be categorized to either synchronous (real-time), asynchronous (whereby data is stored and forwarded subsequently) and continuous (remote monitoring). In diabetes care, all forms of telemedicine services have been examined and include using mobile phones, texting, emails, e-health portals, videoconferencing as well as devices.²⁰

However, implementation of a telemedicine service in conventional care is a complex process. Studies have shown that while telemedicine can expand the boundaries of care to a larger population and offer person-centred care,²¹ there are examples of patient resistance to change.^{22 23} Nevertheless, one of the major limitation of existing literature is the lack of studies which has examined the perspective of patients from a low and middle income country, where telemedicine is now increasingly being used. Therefore, the goal of this study was to explore patients' views and experiences of telemedicine for diabetes management in Malaysia.

Materials and Methods

Study design

The present qualitative study was part of a larger multi-centre cluster randomized controlled study, IDEAS conducted between April 2015 to June 2017 which aimed to examine the impact of a telemedicine program for people with type 2 diabetes (Box 1).²⁴ This nested study design allowed the investigators to explore the facilitators and barriers to using telemedicine, as well as participants' view if telemedicine was implemented in routine practice.

Participants

Participants were recruited from eleven primary care clinics located within the Klang Valley, which is part of the Ministry of Health Malaysia's primary care clinic network. These clinics serves the districts of Klang and Petaling, which provides care for approximately 2.56 million individuals and can be considered to be nationally representative of primary care clinics in Malaysia.

On completion of the IDEAS trial, participants from the trial were invited to participate in the current qualitative study. All potentially eligible participants were contacted by telephone and invited to participate in the qualitative study. Participants were briefed regarding the purpose, procedure and nature of the study and allowed to clarify their doubts. A separate information sheet and written informed consent were obtained prior to participation. All focus groups interviews were conducted at the respective health

1
2
3 clinic, when participants visited the clinics for their follow-up sessions with their
4
5 physicians to accommodate participants' schedule. In the event that a participant was
6
7 not able to attend a focus group session, an individual in-depth interview was
8
9 conducted at their own home. Study participants were incentivized with a RM50
10
11 (approximately USD\$12) voucher for their participation.
12
13
14
15
16

17 **Interview schedule**

18
19
20
21 A semi-structured interview was used in all the focus groups, which was based on an
22
23 interview guide. Table 1 outlines the topic areas and key questions which were used
24
25 during the discussions. The topic guide aimed to capture the experiences of patients
26
27 in using telemedicine and was developed based on relevant literature.^{8 10 23}
28
29
30
31
32

33 The interviews were conducted either in the Malay or English language, which was
34
35 facilitated by the first author (JYL). The interviews usually lasted between 35 - 44
36
37 minutes in an undisturbed room in the clinic. All interview sessions were digitally
38
39 recorded, transcribed verbatim immediately after the interview and checked for
40
41 accuracy by SWHL. Interviews were conducted to explore for emerging themes with
42
43 simultaneous analysis of data until data saturation was achieved, when no new
44
45 themes or codes were identified.
46
47
48
49
50

51 **Data analysis**

52
53 The NVivo software version 11 (QSR International Pty Ltd) was used to organized and
54
55 code the data for thematic analysis.²⁵ All transcripts were read several times to
56
57 familiarize with the data. Transcripts were translated from Malay language to English
58
59
60

1
2
3 by an independent research assistant. The translated English transcripts were double
4
5 checked by one of the authors (JYL) and any discrepancies were resolved via
6
7 discussion with another of the authors (SWHL). The data were subsequently coded,
8
9 based upon keywords or phrases that appeared to convey an opinion or perception
10
11 regarding telemedicine. These initial codes were further examined and refined, with
12
13 codes combined to be main themes if they had similar contexts or split into subthemes.
14
15 The final codes were summarized, cross checked and iteratively refined using paired
16
17 analysis of transcripts by two researchers (JYL and SWHL). In the event that there
18
19 was a divergent interpretation, the transcripts were reviewed again and discussed until
20
21 consensus was achieved.
22
23
24
25
26
27

28 **Ethics**

29
30 The study was approved by the Monash University Research Ethics Committee
31
32 (CF14/1977 – 2014001016 & CF15/1073 - 2015000502) and the National Medical
33
34 Research Register (NMRR-14-177-19466 & NMRR-14-1368-22943). All participants
35
36 provided written informed consent for participation in the research. This study was
37
38 registered with ClinicalTrials.gov under the registration NCT0246680.

44 **Patient and public involvement**

45
46 The current study was designed to understand the patients' views, perception and
47
48 experience of using telemedicine for type 2 diabetes management. Patients were not
49
50 involved in the initial design of the study, development of interview questions or
51
52 conduct of study. All participants who participated in this qualitative study were not
53
54 provided with the results but were informed that the results will be published in a
55
56 peer-review journal.
57
58
59
60

Results

Demographics of participants

A total of 48 participants were interviewed in the 12 focus group (average 3-4 participants per group) and 2 interview sessions. The participants were mostly females (56.3%), with a mean age of 51.9 years, and a mean duration of diabetes of 5.6 years (Table 2). Four core themes emerged from the focus groups and the two in-depth interviews: (1) Generational difference (2) Independence and convenience, (3) Sharing health data and privacy; and (4) Concerns and challenges

Theme 1 – Generational differences

We noted that there were generational differences with regards to their preference on how to record their blood glucose reading. In general, older participants (those aged 50 years and above) preferred to record their glucose readings manually, using pen and paper. They found that using a telemonitoring device required a lot of technical know-how and this was a challenging and complex process. As explained by the participants:

I (prefer to) manually record (my blood glucose readings). I do not understand (how to operate the mobile) telephone especially opening (the software). To me manual (recording) is easier. [Patient 4, 59/F].

But I am an old person (and so) I like it (blood glucose results) to be written. I'm old (and) I need to write (the results) down. Anyway as long as someone

1
2
3 shows me how to do it I can do it. Of course (using telemedicine) is easier
4
5 because you bring your hand phone everywhere you go. [Patient 5, 57/F]
6
7
8
9

10 These participants felt that the use of telemedicine was more suitable for younger
11 people with diabetes who were more technology savvy. As explained by one
12 participant, “Maybe for the young ones (lah). Technology (is) for youngsters (and) is
13 more suitable since they like to sit at home and like the thing called Internet. [Patient
14 41, 67/M]” Some participants also expressed their preference to meet their health care
15 providers in person and reported that travelling to the clinic was not an onerous task.
16
17
18
19
20
21
22
23
24
25

26 I don't mind coming to the clinic and have a chat with the doctor. We (can)
27 discuss (my medical condition) and sometimes we can ask questions and
28 doctors can show (my problem to me) physically. For me to use the Internet
29 is difficult to learn (as) my children are not here. [Patient 6, 60/M].
30
31
32
33
34
35
36
37

38 Conversely, younger participants were more inclined to learn and use new
39 technologies if sufficient training and guidance were given. Additionally, they were
40 optimistic about using telemedicine to manage their conditions, as they knew the
41 various benefits that technology would provide, including data tracking ability and
42 convenience.
43
44
45
46
47
48
49
50

51 **Theme 2 – Independence and convenience**

52 Participants expressed that the use of a mobile phone which is connected to a
53 glucometer is a convenient alternative for the management of diabetes. Participants
54 viewed that it is a more convenient option in the event of time constraints and a lack
55
56
57
58
59
60

1
2
3 of transportation to the clinic. Participants also revealed that having a telemonitoring
4 device encouraged them to monitor their glucose levels regularly compared to the
5 quarterly check-ups at the clinic. As expressed by one participant “It’s good to use
6 especially over the Internet. It’s so much easier we do not have to come to the clinic
7 and can stay at home [Patient 12, 60/M]”.

8
9
10
11
12
13
14
15
16
17 Digitals way (is the preferred choice). Everyday you can see (your blood
18 glucose results) in the software so (there is) no need to record like
19 manual. Sometime even you record manual the paper will go wherever
20 (or) missing. (Using) digital you have a backup. [Patient 8, 35/F]

21
22
23
24
25
26
27
28 I like this because you can transfer (your blood glucose results)
29 directly to your phone. It’s useful to me as an indication. I prefer (using
30 technology so) that I can use it to check how my medicine affects my
31 glucose. I think that this is the best tools because you can monitor by
32 the Internet everywhere you go. [Patient 9, 44/M]

33
34
35
36
37
38
39
40
41
42 It’s even more convenient since we do not have the time to come (to the
43 clinic) and sometimes some people do not have transport. [Patient 10,
44
45
46
47 44/F]

48
49
50
51 Most participants were generally enthusiastic as they saw the potential benefits of
52 telemedicine. Participants described how the use of a web-based glucometer was
53 useful as it could provide them with reminders and alerts as well as the ability to
54 connect with their healthcare providers without going to the clinic. Nevertheless, they
55
56
57
58
59
60

1
2
3 expressed the desire and need to have more training and assistance, especially when
4 they had not used the device for some time, since they would have forgotten how it
5 functions and to use.
6
7
8
9

10
11
12 For me it's not difficult ... just need to teach (me) that's all. See the learning
13 condition first (and perhaps I need more training), maybe need two or three
14 times. I'm over fifty (years old) so (the) first time will be a problemneed
15 to teach a few times before I understand. First time might be difficult to
16 understand. [Patient 7, 56/M]
17
18
19
20
21
22
23
24
25
26
27
28
29

30 31 **Theme 3 – Sharing health data and privacy**

32
33
34
35 Our analysis showed that there was some conflicting perspective with data sharing.
36 Several participants expressed that they were willing to share their monitoring results
37 with family members, as they felt that the family member would make them
38 accountable for their diabetes management, which was a significant motivation for
39 them to meet their daily goals.
40
41
42
43
44
45
46
47
48

49 The use of this what you call it (web-telemonitor)..... my health is good
50 especially when family members want to monitor your sugar control can
51 monitor as well. [Patient 11, 54/F]
52
53
54
55
56
57
58
59
60

1
2
3 The good part (of telemedicine is) you can do it at home. If (you check
4 your blood glucose levels) at the clinic you get pricked (but) nobody
5 knows (the results)... but when you do it at home you children will be
6 informed as well. [Patient 5, 57/F]
7
8
9
10
11
12
13
14
15
16

17 Conversely, some participants expressed concern that the sharing of medical
18 information with their family members might infringe on their personal space and could
19 potentially cause conflicts between family members.
20
21
22
23
24
25

26 That thing is okay but what I am afraid of is (that the use of telemonitoring may)
27 sometimes (cause) conflicts because it feels like you are being monitored by
28 others. But it is beneficial, at least there is somebody remind you. [Patient 1,
29 45/M]
30
31
32
33
34
35
36
37

38 Participants expressed concern they had about the presence of malware in
39 telemonitoring devices that could compromise their personal information.
40
41
42
43

44 (What happens when we have a) problem with the Internet (connection).
45 Occasionally we (may) receive the reading, but occasionally (we will be) unable
46 to (do so). (This can be) very inconvenient. [Patient 11, 54/F].
47
48
49
50
51
52
53
54
55

56 Some participants felt that meeting or contacting their health care providers was a
57 simpler and faster way to solve their queries as the health care practitioners would
58
59
60

1
2
3 be able to explain their clinical measures in a more concise manner. As explained by
4 one participant “Face-to face (consultation) is more important (as) its better. (With)
5 face-to face (consultation), information is clearer and more satisfying to me. [Patient
6 2, 67F].”
7
8
9
10
11
12
13

14 **Theme 4 – Concerns and challenges**

15
16
17
18
19 Participants in this study emphasized the importance of having a user-friendly
20 technology. Most participants in this study reported minor technical difficulties
21 especially with internet connectivity and availability especially in rural areas, which
22 limited their ability to utilize the telemonitoring device effectively. Participants also
23 expressed concerns regarding the stability of Internet connection at their homes.
24
25
26
27
28
29
30
31
32

33 I think depend on the situation.. whether you live in a village where it will be
34 very difficult..... because (in) certain villages you don't have (Internet) line so
35 you still need have (to record the blood glucose results) manually. [Patient 8,
36 35/F]
37
38
39
40
41
42
43

44 Participants suggested the need to have a robust system which is user-friendly, has
45 good technical support which they felt was essential to ensure that the implementation
46 of telemedicine was successful.
47
48
49
50
51
52

53 “Okay (lah) but what happens when there is a virus? It is a problem for one
54 week my handphone “hang”. After one week it hang (again)....that is a problem”
55
56
57
58 [Patient 13, 54/F].
59
60

1
2
3
4
5 Another aspect which participants were worried of was the costs involved compared
6 to conventional care and that telemonitoring would only be suitable for affluent
7 patients.
8
9
10
11
12
13

14 All this (telemedicine) is for people who are wealthy. Of course this is a good
15 system. [Patient 14, 63/M]

Discussion

In our study, we present the conditions for the success of a telemonitoring health device for managing type 2 diabetes, from patients' perspective. We identified a set of distinctive but interrelated conditions which are central to the success of such programs. Firstly, participants' demographics played a crucial factor in ensuring the acceptability of telemedicine. We noted that younger participants between the ages of 29 to 50 years old preferred using a web-based glucometer compared to older participants who preferred recording their results manually. Such outcome is not surprising as young individuals who grew up in this digital era were usually more technologically savvy compared to their older counterparts.^{26 27} Participants cited various reasons for being unable to use a web-based glucometer, including the lack of Internet connection especially in the rural areas. Indeed, concerns about the stability of Internet connection was the biggest barrier in using telemedicine in diabetes care in this study. The need for a simple, user friendly technology was also consistently highlighted, to encourage acceptability among participants to use a remote telemonitoring system.

As telemedicine technology is improving continuously, participants expressed enthusiasm on the potential added value of telemedicine. Most participants were willing to incorporate technology as part of their diabetes management, but expressed the need to have sufficient training and on-going support, especially when they encountered issues such as equipment limitations. Our study also identified the potential benefits which fueled participants' enthusiasm towards telemedicine. These include receiving alerts, being able to respond to SMBG readings with advice from a health care professional; as well as reducing opportunity cost incurred when using

1
2
3 telemedicine.²⁸ Our study also offers an additional perspective and insight into the
4 importance of patient-provider relationship. Our results support previous research
5 which indicated that personal interaction with a health care practitioner was an
6 important aspect to support type 2 diabetes patients, especially when it involves
7 SMBG.²⁹ This view was also expressed by most participants in the present study, and
8 also that a lack of emotional support especially when communicating through remote
9 telemonitoring resulted in participants dropping out of the study.¹³

10
11
12
13
14
15
16
17
18
19
20
21 Our study also noted that not all participant perceive enhanced SMBG as a positive
22 tool to help achieve good glycaemic control. Some participants in this study expressed
23 reservation on the feedback and monitoring feature, which they felt intruded into their
24 personal space. They also expressed some tension between achieving good
25 glycaemic control and quality of life, especially with the involvement of health care
26 providers and family members whom they felt were acting as a “police”. As a results,
27 some of these patients opted not to take part in the randomized controlled trial, for fear
28 that this could further amplify the tension and strain the relationship, an outcome which
29 they definitely did not want. Findings of this study identified several issues which are
30 salient in the literature. For example, our study like many others noted that patients
31 were acceptable to telemedicine due to its ability to reduce travel time, increase self-
32 awareness and access to care. However, our study also found several additional
33 barriers that have never been reported in literature, such as the tensions between
34 operational practicality versus patient’s privacy and health security.

1
2
3 Our study offers several strength. By exploring the insights of patients, we illustrate
4 how family values and technology literacy could influence participants' opinion on
5 telemonitoring. Our study was also culturally specific to an Asian context and thus, we
6 could gain an in-depth understanding and broader views of participants' behaviors
7 when managing diabetes. There were some limitations to our study. Firstly, although
8 we had included a diverse sample of participants and reached thematic saturation in
9 our focus groups and in-depth interviews, these participants were only limited to one
10 geographical location in Malaysia. Participants in this current study were recruited
11 from suburban districts in Selangor where connectivity and technology literacy were
12 moderate. Future studies should include patients from both urban as well as rural
13 location and those with high technology literacy, as this could potentially influence the
14 uptake and acceptability of telemedicine. While published literature suggest that these
15 trends are likely to be transferable to other regions in Malaysia, the context may differ
16 in other countries and settings. The views expressed here are solely from a patients'
17 point and does not represent the views of health care providers or policy makers.
18 Finally, our results cannot draw definitive conclusion regarding differences in provider
19 practices, patient knowledge as well as attitudes from different clinic sites other than
20 those examined in this study.

49 **Implications for practice**

50
51 The continual improvements in technology will facilitate the use of telemedicine in
52 future. The largest implication will be its ability to reduce logistical barriers and time
53 saving potential. However, it is important that any telemedicine programs consider
54 the economic standing of patients, especially those living in rural areas, who may
55
56
57
58
59
60

1
2
3 have limited internet connectivity. As such, health care professionals and policy
4
5 makers need to take into consideration these aspects prior to introducing any
6
7 telemedicine technology for their patients to ensure that patients' expectations are
8
9 met. Another theme that emerged from this interview was the need to invest in
10
11 capacity building especially in human resources. Specifically, the creation of training
12
13 programs for both public as well as health workers are particularly important,
14
15 especially among the non-IT savvy groups.

Conclusion

In conclusion, findings from this study indicate that the implementation of telemonitoring requires strategic planning with inputs from various stakeholders including, educators, health care providers, telco service providers and patients. These need to take into consideration the patient's personal and contextual factors, which could have a positive or negative effect. As such, health care providers need to discuss patients' perspective to ensure the optimal use of telemedicine to improve patients' clinical parameters and quality of life.

Box 1: IDEAS study

The Intervention for Diabetes with Education, Advancement and Support (IDEAS) study is a cluster randomized controlled study to evaluate the use of telemedicine to improve diabetes care. Participants in the telemedicine group were instructed to measure their blood glucose at least twice weekly (one fasting and one non-fasting) or more frequent as recommended by physician. These blood glucose readings will be transmitted via a Bluetooth technology to the participants' mobile phone to a remote secure server. Participants and their physicians were able to access the records on the server. Advice on lifestyle modification, any potential changes in medication, who and how to contact their healthcare providers were also given monthly during the study. A researcher also checked participants' results weekly and initiate intervention if needed (e.g. medication changes, counselling) with the consent of the attending physician.

Standards for Reporting Qualitative Research (SRQR)*

<http://www.equator-network.org/reporting-guidelines/srqr/>

Page/line no(s).

Title and abstract

<p>Title - Concise description of the nature and topic of the study Identifying the study as qualitative or indicating the approach (e.g., ethnography, grounded theory) or data collection methods (e.g., interview, focus group) is recommended</p>	1
<p>Abstract - Summary of key elements of the study using the abstract format of the intended publication; typically includes background, purpose, methods, results, and conclusions</p>	3

Introduction

<p>Problem formulation - Description and significance of the problem/phenomenon studied; review of relevant theory and empirical work; problem statement</p>	6-7
<p>Purpose or research question - Purpose of the study and specific objectives or questions</p>	7

Methods

<p>Qualitative approach and research paradigm - Qualitative approach (e.g., ethnography, grounded theory, case study, phenomenology, narrative research) and guiding theory if appropriate; identifying the research paradigm (e.g., postpositivist, constructivist/ interpretivist) is also recommended; rationale**</p>	9
<p>Researcher characteristics and reflexivity - Researchers' characteristics that may influence the research, including personal attributes, qualifications/experience, relationship with participants, assumptions, and/or presuppositions; potential or actual interaction between researchers' characteristics and the research questions, approach, methods, results, and/or transferability</p>	9
<p>Context - Setting/site and salient contextual factors; rationale**</p>	8
<p>Sampling strategy - How and why research participants, documents, or events were selected; criteria for deciding when no further sampling was necessary (e.g., sampling saturation); rationale**</p>	8
<p>Ethical issues pertaining to human subjects - Documentation of approval by an appropriate ethics review board and participant consent, or explanation for lack thereof; other confidentiality and data security issues</p>	10
<p>Data collection methods - Types of data collected; details of data collection procedures including (as appropriate) start and stop dates of data collection and analysis, iterative process, triangulation of sources/methods, and modification of procedures in response to evolving study findings; rationale**</p>	8-9

1 2 3 4 5	Data collection instruments and technologies - Description of instruments (e.g., interview guides, questionnaires) and devices (e.g., audio recorders) used for data collection; if/how the instrument(s) changed over the course of the study	9 & Table 1
6 7 8	Units of study - Number and relevant characteristics of participants, documents, or events included in the study; level of participation (could be reported in results)	11
9 10 11 12	Data processing - Methods for processing data prior to and during analysis, including transcription, data entry, data management and security, verification of data integrity, data coding, and anonymization/de-identification of excerpts	9
13 14 15 16	Data analysis - Process by which inferences, themes, etc., were identified and developed, including the researchers involved in data analysis; usually references a specific paradigm or approach; rationale**	9-10
17 18 19 20	Techniques to enhance trustworthiness - Techniques to enhance trustworthiness and credibility of data analysis (e.g., member checking, audit trail, triangulation); rationale**	10

Results/findings

23 24 25 26	Synthesis and interpretation - Main findings (e.g., interpretations, inferences, and themes); might include development of a theory or model, or integration with prior research or theory	11-17
27 28 29	Links to empirical data - Evidence (e.g., quotes, field notes, text excerpts, photographs) to substantiate analytic findings	11-17

Discussion

32 33 34 35 36 37	Integration with prior work, implications, transferability, and contribution(s) to the field - Short summary of main findings; explanation of how findings and conclusions connect to, support, elaborate on, or challenge conclusions of earlier scholarship; discussion of scope of application/generalizability; identification of unique contribution(s) to scholarship in a discipline or field	18-20
38 39	Limitations - Trustworthiness and limitations of findings	21

Other

42 43 44	Conflicts of interest - Potential sources of influence or perceived influence on study conduct and conclusions; how these were managed	22
45 46	Funding - Sources of funding and other support; role of funders in data collection, interpretation, and reporting	23

*The authors created the SRQR by searching the literature to identify guidelines, reporting standards, and critical appraisal criteria for qualitative research; reviewing the reference lists of retrieved sources; and contacting experts to gain feedback. The SRQR aims to improve the transparency of all aspects of qualitative research by providing clear standards for reporting qualitative research.

Consolidated criteria for reporting qualitative studies (COREQ): 32-item checklist

Developed from:

Tong A, Sainsbury P, Craig J. Consolidated criteria for reporting qualitative research (COREQ): a 32-item checklist for interviews and focus groups. *International Journal for Quality in Health Care*. 2007. Volume 19, Number 6: pp. 349 – 357

No. Item	Guide questions/description	Reported on Page #
Domain 1: Research team and reflexivity		
<i>Personal Characteristics</i>		
1. Inter viewer/facilitator	Which author/s conducted the inter view or focus group?	9
2. Credentials	What were the researcher's credentials? E.g. PhD, MD	1
3. Occupation	What was their occupation at the time of the study?	1
4. Gender	Was the researcher male or female?	1
5. Experience and training	What experience or training did the researcher have?	9
<i>Relationship with participants</i>		
6. Relationship established	Was a relationship established prior to study commencement?	10
7. Participant knowledge of the interviewer	What did the participants know about the researcher? e.g. personal goals, reasons for doing the research	8
8. Interviewer characteristics	What characteristics were reported about the inter viewer/facilitator? e.g. Bias, assumptions, reasons and interests in the research topic	9

Domain 2: study design		
<i>Theoretical framework</i>		
9. Methodological orientation and Theory	What methodological orientation was stated to underpin the study? e.g. grounded theory, discourse analysis, ethnography, phenomenology, content analysis	9-10
<i>Participant selection</i>		
10. Sampling	How were participants selected? e.g. purposive, convenience, consecutive, snowball	8
11. Method of approach	How were participants approached? e.g. face-to-face, telephone, mail, email	8-9
12. Sample size	How many participants were in the study?	8
13. Non-participation	How many people refused to participate or dropped out? Reasons?	8
<i>Setting</i>		
14. Setting of data collection	Where was the data collected? e.g. home, clinic, workplace	11
15. Presence of non-participants	Was anyone else present besides the participants and researchers?	11
16. Description of sample	What are the important characteristics of the sample? e.g. demographic data, date	11
<i>Data collection</i>		
17. Interview guide	Were questions, prompts, guides provided by the authors? Was it pilot tested?	Table 1
18. Repeat interviews	Were repeat inter views carried out? If yes, how many?	No
19. Audio/visual recording	Did the research use audio or visual recording to collect the data?	9-10
20. Field notes	Were field notes made during and/or after the inter view or focus group?	No
21. Duration	What was the duration of the inter views or focus group?	9

22. Data saturation	Was data saturation discussed?	9
23. Transcripts returned	Were transcripts returned to participants for comment and/or correction?	No
Domain 3: analysis and findings		
<i>Data analysis</i>		
24. Number of data coders	How many data coders coded the data?	10
25. Description of the coding tree	Did authors provide a description of the coding tree?	10
26. Derivation of themes	Were themes identified in advance or derived from the data?	No
27. Software	What software, if applicable, was used to manage the data?	9
28. Participant checking	Did participants provide feedback on the findings?	10
<i>Reporting</i>		
29. Quotations presented	Were participant quotations presented to illustrate the themes/findings? Was each quotation identified? e.g. participant number	Yes. 11-17
30. Data and findings consistent	Was there consistency between the data presented and the findings?	18-20
31. Clarity of major themes	Were major themes clearly presented in the findings?	Yes. they were. 11-20
32. Clarity of minor themes	Is there a description of diverse cases or discussion of minor themes?	Discussion of major and minor themes 18-20

Abstract

Objective: Telemedicine has been promoted as an economical and effective way to enhance patient care but its acceptability among patients in low and middle income countries is poorly understood. This study aims to explore the experiences and perspectives of people with type 2 diabetes mellitus who used telemedicine to manage their condition.

Design: We conducted in-depth and focus group interviews with participants who used telemedicine. Questions included participants' perception on program use, satisfaction as well as engagement with the telemedicine program. All interviews and focus groups were audio-recorded and transcribed verbatim. Data were analyzed using a thematic approach.

Participants and setting: People with type 2 diabetes (n=48) who participated in a randomized controlled study which examined the using telemedicine for diabetes management.

Results: Twelve focus groups and two in-depth interviews were conducted. Four themes emerged from the analysis: (1) Generational difference (2) Independence and convenience, (3) Sharing of health data and privacy; and (4) Concerns and challenges. The main barriers to using telemedicine were related to the user friendliness of the devices as well as internet connectivity. Cost was also another significant concern raised by participants. However, participants were generally positive about the benefits of telemedicine, including its ability to provide real time data and disease monitoring and the reduction in clinic visits.

Conclusion: Despite the potential positive benefits of using telemedicine for diabetes care, several barriers could inhibit the sustained and effective use of this technology.

1
2
3 As such, collaboration between educators, health care providers, telecommunication
4 service providers and patients is required to stimulate telemedicine adoption and use.

Strengths and limitations of this study

- Article followed the Standards for reporting qualitative Research (SRQR) recommendations on reporting
- Focus group discussion allowed the exchange of opinions about telemedicine, leading to richer information
- View and experiences of using telemedicine from patients only were captured rather than that of healthcare providers
- The study was conducted in an urban setting in Malaysia and its applicability and transferability to other population remain unknown.

Introduction

Diabetes is a major health concern worldwide, and according to a recent report by the International Diabetes Federation, the global prevalence of diabetes will increase from 415 million in 2015 to 642 million in 2040.¹ The prevalence varies considerably between different regions, but the epicenter of the diabetes crisis is currently located in the Western Pacific and South-East Asia region, with 159 million and 82 million individuals with diabetes respectively.² In many individuals with diabetes, self-monitoring of blood glucose (SMBG) is considered as a key component of treatment, and widely recommended by clinical practice guidelines, irrespective of treatment strategy.³⁻⁷ SMBG is often used as an early warning sign for detecting hypoglycaemia, for improving the recognition of severe hyperglycaemia, to encourage physical activities as well as improve diet control. These data are also often used by the treating physicians to facilitate an individualized treatment regimen.

Despite these potential benefits, there is controversy on the efficacy of SMBG, especially in non-insulin dependent type 2 diabetes, due to its cost, uncertainty on frequency of testing as well as impact on patients' general health and well-being.⁸⁻¹⁰ Studies have shown that the use of enhanced SMBG (where there are high levels of engagement between patients and clinicians to interpret the SMBG values) resulted in larger reduction in HbA1c compared to regular SMBG.^{4 11-13}

The application of telemedicine, or technology to deliver various aspects of health information, prevention, monitoring and medical care in diabetes management has been suggested as an innovative solution to improve diabetes care.¹⁴⁻¹⁶ Increasingly,

1
2
3 telemedicine is being viewed as a promising technology in assisting patients to
4 manage their diabetes,^{15 17 18} as it produces accurate and reliable data¹⁹, empowers
5 patients¹⁴, improves glycaemic control and influences their attitude and behaviours¹⁸

telemedicine is being viewed as a promising technology in assisting patients to manage their diabetes,^{15 17 18} as it produces accurate and reliable data¹⁹, empowers patients¹⁴, improves glycaemic control and influences their attitude and behaviours¹⁸²⁰, potentially leading to a better quality of life.²¹ Additionally, telemedicine has the potential to reduce the barrier to adherence of self-management through real-time data transfer between patient and provider, the review of blood glucose measurement trends, and a reduction in opportunity costs. These telemedicine services can be categorized to either synchronous (real-time), asynchronous (whereby data is stored and forwarded subsequently) and continuous (remote monitoring). In diabetes care, various forms of telemedicine services have been examined and include using mobile phones, texting, emails, e-health portals, videoconferencing as well as remote monitoring devices.

However, implementation of a telemedicine service in conventional care is a complex process. Studies have shown that while telemedicine can expand the boundaries of care to a larger population and offers person-centred care,²² there are examples of patients' resistance to change.^{23 24} Nevertheless, one of the major limitations of existing literature is the lack of studies which have examined the perspective of patients from a low and middle income country, where telemedicine is now increasingly being used. Earlier work on this topic have mostly focused on the views of physicians and fewer studies have at looked the patient's perspective.^{25 26} In most of these studies, there was limited understanding on the drivers and barriers that were faced by patients using telemedicine; and have mostly focused on the telemedicine technology as well as utilization rates of telemedicine.^{24 27} Furthermore, very little is known as to how empirically supported interventions can be transferred or

1
2
3 implemented in resource-constraint countries, i.e., in most developing countries.
4
5 Understanding the behaviors among various levels of stakeholders is an important
6
7 component of successful implementation research.²⁸
8
9
10
11
12
13

14 As patients' experience with telemedicine may be one of the reasons that will
15
16 determine the success or failure of any intervention, we conducted a qualitative study
17
18 to explore patients' views and experiences of telemedicine for diabetes management
19
20 in Malaysia. The study focused on the end users' perspective in context which were
21
22 necessary to ensure the successful delivery and implementation of a telemedicine
23
24 program for diabetes.

Materials and Methods

Study design

The present qualitative study was part of a larger multi-centre cluster randomized controlled study, (IDEAS) conducted between April 2015 to June 2017, which aimed to examine the impact of a telemedicine program for people with type 2 diabetes (Box 1).²⁹ This nested study design allowed the investigators to explore the facilitators and barriers to using telemedicine, as well as participants' view if telemedicine was implemented in routine practice.

Participants

Participants were recruited from eleven primary care clinics located within the Klang Valley, which is part of the Malaysian Ministry of Health's primary care clinic network. These clinics serve the districts of Klang and Petaling, which provides care for approximately 2.56 million individuals and can be considered to be nationally representative of primary care clinics in Malaysia.

In line with the qualitative nature of our study, we adopted a non-probability sampling approach, in which sampling was not guided by the idea of random selection or statistical representativeness. Nevertheless, we aimed to cover as broad a spectrum of participants who had experience using telemedicine, as possible. As such, we invited participants who had completed the IDEAS study to participate in the current qualitative study. Briefly, participants included those who: 1) had been diagnosed with

1
2
3 type 2 diabetes for at least 6 months; 2) aged between 18-75 years; 3) had regular
4 access to the internet; 4) had HbA1c levels of between 7.5% and 11.0; and 5) were
5
6 randomized into the intervention arm of the IDEAS study²⁹. Participants were excluded
7
8 if they had no experience in using any telemedicine devices or had dropped out of the
9
10 IDEAS study. All potentially eligible participants were contacted by telephone and
11
12 invited to participate in the qualitative study. Participants were briefed regarding the
13
14 purpose, procedure and nature of the study and allowed to clarify their doubts.
15
16 Separate information sheet and written informed consent were obtained prior to
17
18 participation. To accommodate participants' schedules, all focus group interviews
19
20 were conducted at the respective health clinics, when participants visited the clinics
21
22 for their follow-up sessions with their physicians. In the event that a participant was
23
24 not able to attend a focus group session, an individual in-depth interview was
25
26 conducted at their own home. Study participants were incentivized with a RM50
27
28 (approximately USD\$12) voucher for their participation.
29
30
31
32
33
34
35
36
37
38

39 **Interview schedule**

40
41
42 A semi-structured interview was used in all the focus groups, which was based on an
43
44 interview guide. Table 1 outlines the topic areas and key questions which were used
45
46 during the discussions. The topic guide aimed to capture the experiences of patients
47
48 in using telemedicine and was developed based on relevant literature.^{10 12 23}
49
50
51
52
53

54 The interviews which was facilitated by the first author (JYL) were conducted either in
55
56 Malay or English language. The interviews usually lasted between 35 and 44 minutes
57
58 in a private room in the clinic. All interview sessions were digitally recorded,
59
60

1
2
3 transcribed verbatim immediately after each interview and checked for accuracy by
4
5 SWHL. Interviews were conducted to explore for emerging themes with simultaneous
6
7 analysis of data until data saturation was achieved, when no new themes or codes
8
9 were identified.
10
11
12
13

14 **Data analysis**

15
16 The NVivo software version 11 (QSR International Pty Ltd) was used to organized and
17
18 code the data for thematic analysis, using both an inductive and deductive approach.³⁰
19
20 All transcripts were read several times to familiarize with the data. Transcripts were
21
22 translated from Malay language to English by an independent research assistant. The
23
24 translated English transcripts were double checked by one of the authors (JYL) and
25
26 any discrepancies were resolved via discussion with another of the authors (SWHL).
27
28 Firstly, transcripts were coded into an initial set of themes based on keywords or
29
30 phrases that appeared to convey an opinion or perception regarding telemedicine
31
32 guided by themes identified previously from previous literature^{10 12 23}. These initial
33
34 codes were further examined and refined, with codes combined to be main themes if
35
36 they had similar contexts or split into subthemes via an inductive process. The final
37
38 codes were summarized, cross checked and iteratively refined using paired analysis
39
40 of transcripts by two researchers (JYL and SWHL). In the event that there was a
41
42 divergent interpretation, the transcripts were reviewed again and discussed until
43
44 consensus was achieved.
45
46
47
48
49

2
3 Research Register (NMRR-14-177-19466 & NMRR-14-1368-22943). All participants
4
5 provided written informed consent for participation in the research. This study was
6
7 registered with ClinicalTrials.gov under the registration NCT0246680.
8
9
10

11 **Patient and public involvement**

12
13
14 The current study was designed to understand the patients' views, perception and
15
16 experience of using telemedicine for type 2 diabetes management. Patients were not
17
18 involved in the initial design of the study, development of interview questions or
19
20 conduct of study. All participants who participated in this qualitative study were not
21
22 provided with the results but were informed that the results will be published in a
23
24 peer-reviewed journal.

Results

Demographics of participants

A total of 48 participants were interviewed in the 12 focus groups (average of 3-4 participants per group) and 2 interview sessions. The participants were mostly females (56.3%), with a mean age of 51.9 years, and a mean duration of diabetes of 5.6 years (Table 2). Four core themes emerged from the focus groups and the two in-depth interviews: (1) Generational difference (2) Independence and convenience, (3) Sharing of health data and privacy; and (4) Concerns and challenges

Theme 1 – Generational differences

Our data suggest that there were generational differences with regards to participants' preference on how to record their blood glucose reading. In general, older participants (those aged 50 years and above) preferred to record their glucose readings manually, using pen and paper. They felt that the telemonitoring device required a lot of technical knowledge and was a challenging and complex process for them. As narrated by the participants:

“I (prefer to) manually record (my blood glucose readings). I do not understand (how to operate the mobile) telephone especially opening (the software). To me manual (recording) is easier.” [Patient 4, 59/F]

“But I am an old lady. I like it (blood glucose results) to be written (down). I'm old (and) I need to write (the results) down. Anyway, as long as someone

1
2
3 shows me how to do it, I can do it. Of course (using telemedicine) is easier
4
5 because you bring your hand phone everywhere you go.” [Patient 5, 57/F]
6
7
8
9

10 These participants felt that the use of telemedicine was more suitable for younger
11 individuals with diabetes who were more technology savvy. As explained by one
12 participant, “Maybe for the young ones . Technology (is) for youngsters (and) is more
13 suitable since they like to sit at home and like the thing called Internet.” [Patient 41,
14
15
16
17
18
19 67/M]
20
21
22
23

24 Some participants also expressed their preference to meet their health care providers
25 in person and reported that travelling to the clinic was not an onerous task.
26
27
28
29

30 “I don't mind coming to the clinic and have a chat with the doctor. We (can)
31 discuss (my medical condition) and sometimes we can ask questions and
32 doctors can show (my problem to me) physically. For me to use the Internet
33 is difficult to learn (as) my children are not here.” [Patient 6, 60/M]
34
35
36
37
38
39
40
41

42 Conversely, younger participants were more inclined to learn and use new
43 technologies if sufficient training and guidance were given. Additionally, they were
44 optimistic about using telemedicine to manage their conditions, as they knew the
45 various benefits that technology would provide, including data tracking ability and
46 convenience.
47
48
49
50
51
52
53
54

55 **Theme 2 – Independence and convenience**

56
57
58
59
60

1
2
3 Participants expressed that the use of a mobile phone which was connected to a
4 glucometer was a convenient alternative for the management of diabetes. Participants
5 viewed it was a more convenient option in the event of time constraint or when they
6 had issues commuting to the clinic for their appointment. Participants also mentioned
7 that having a telemonitoring device encouraged them to monitor their glucose levels
8 regularly compared to the quarterly check-ups at the clinic. As expressed by
9 participants
10
11
12
13
14
15
16
17
18
19
20
21

22 “It’s good to use especially over the Internet. It’s so much easier we do not have
23 to come to the clinic and can stay at home” [Patient 12, 60/M].
24
25
26
27

28 “Digital way (is the preferred choice). Everyday you can see (your
29 blood glucose results) in the software so (there is) no need to record
30 like manual. Sometimes even you record manual the paper will go
31 wherever (or) missing. (Using) digital you have a backup.” [Patient 8,
32 35/F]
33
34
35
36
37
38
39
40
41

42 “I like this because you can transfer (your blood glucose results)
43 directly to your phone. It’s useful to me as an indication. I prefer (using
44 technology so) that I can use it to check how my medicine affects my
45 glucose. I think that this is the best tools because you can monitor by
46 the Internet everywhere you go.” [Patient 9, 44/M]
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 “It’s even more convenient since we do not have the time to come (to
4 the clinic) and sometimes some people do not have transport.” [Patient
5
6
7
8 10, 44/F]
9

10
11
12 Most participants were generally enthusiastic as they saw the potential benefits of
13 telemedicine. Participants described how the use of a web-based glucometer was
14 useful as it could provide them with reminders and alerts as well as the ability to
15 connect with their healthcare providers without going to the clinic. Nevertheless, they
16 expressed the desire and need to have more training and assistance, especially when
17 they had not used the device for some time, since they would have forgotten the
18 functions on the device.
19
20
21
22
23
24
25
26
27
28
29

30
31 “For me it’s not difficult ... just need to teach (me) that’s all. See the learning
32 condition first (and perhaps I need more training), maybe need two or three
33 times. I’m over fifty (years old) so (the) first time will be a problemneed
34 to teach a few times before I understand. First time might be difficult to
35 understand” [Patient 7, 56/M].
36
37
38
39
40
41
42
43
44
45
46
47
48

49 **Theme 3 – Sharing health data and privacy**

50
51
52

53 Our analysis showed that there were conflicting perspectives with data sharing.
54 Several participants expressed that they were willing to share their monitoring results
55 with family members, as they felt that the family member would make them
56
57
58
59
60

1
2
3 accountable for their diabetes management, which was a significant motivation for
4
5 them to meet their daily goals.
6
7
8
9

10 “The use of this what you call it (web-telemonitor)..... (I feel) my health
11
12 is better since my family members (also) monitors (my) sugar levels as
13
14 well” [Patient 11, 54/F].
15
16
17
18

19 “The good part (of telemedicine is) you can do it at home. If (you check
20
21 your blood glucose levels) at the clinic you get pricked (but) nobody
22
23 knows (the results)... but when you do it at home you children will be
24
25 informed as well” [Patient 5, 57/F].
26
27
28
29
30
31
32

33 Conversely, some participants expressed concern on the sharing of medical
34
35 information with their family members, which they felt their personal space was
36
37 infringed and could potentially lead to conflicts between family members.
38
39
40
41

42 “That thing (Telemonitoring device) is okay (to use) but what I am afraid of is
43
44 (that the use of telemonitoring may) sometimes (cause) conflicts because it
45
46 feels like you are being monitored by others. But it is beneficial, at least there
47
48 is somebody remind you” [Patient 1, 45/M].
49
50
51
52

53 Participants also expressed concern about the presence of malware in
54
55 telemonitoring devices that could compromise their personal information.
56
57
58
59
60

1
2
3 “(What happens when we have a) problem with the Internet (connection).
4
5 Occasionally we (may) receive the reading, but occasionally (we will be) unable
6
7 to (do so). (This can be) very inconvenient” [Patient 11, 54/F].
8
9

10
11
12
13
14
15 Some participants felt that meeting or contacting their health care providers was a
16
17 simpler and faster way to solve their queries as the health care practitioner would be
18
19 able to explain their clinical measures in a more concise manner. As explained by
20
21 one participant “Face-to face (consultation) is more important (as) its better. (With)
22
23 face-to face (consultation), information is clearer and more satisfying to me.” [Patient
24
25 2, 67F].
26
27
28
29

30 **Theme 4 – Concerns and challenges**

31
32
33
34
35 Participants in this study emphasized the importance of having a user-friendly
36
37 technology. Most participants in this study reported minor technical difficulties
38
39 especially with Internet connectivity and availability in rural areas, which limited their
40
41 ability to utilize the telemonitoring device effectively. Participants also expressed
42
43 concerns regarding the stability of Internet connection at their homes.
44
45
46
47
48

49 “I think depending on the situation.. whether you live in a village where (I feel)
50
51 it will be very difficult..... because (in) certain villages you don't have (Internet)
52
53 line so you (will) still need have (to record the blood glucose results) manually”
54
55 [Patient 8, 35/F].
56
57
58
59
60

1
2
3 Participants suggested the need to have a robust system which is user-friendly, with
4
5 good technical support which they felt were essential to ensure the successful
6
7 implementation of telemedicine.
8
9

10
11
12 “Okay but what happens when there is a virus? It is a problem for one week my
13
14 handphone “hang”. After one week it hangs (again)...that is a problem” [Patient
15
16 13, 54/F].
17
18
19

20
21 Another aspect which participants were worried of was the costs involved compared
22
23 to conventional care and that telemonitoring would only be suitable for affluent
24
25 patients.
26
27
28
29

30
31 “All this (telemedicine) is for people who are wealthy. Of course this is a good
32
33 system.” [Patient 14, 63/M]

Discussion

In our study, we present the conditions for the success of a telemonitoring health device for managing type 2 diabetes, from patients' perspective. We identified a set of distinctive but interrelated conditions which were and will be central to the success of such programs in the context of a developing country. Firstly, participants' demographics played a crucial factor in ensuring the acceptability of telemedicine. We noted that younger participants between the ages of 29 and 50 years old preferred using a web-based glucometer compared to older participants who preferred recording their results manually. Such outcome is not surprising as young individuals who grew up in this digital era were usually more technologically savvy compared to their older counterparts. Participants cited various reasons for being unable to use a web-based glucometer, including the lack of Internet connectivity especially in the rural areas. Indeed, concerns about the stability of Internet connections were the biggest barrier in using telemedicine in diabetes care in this study. The need for a simple, user friendly technology was also consistently highlighted, to encourage acceptability among participants to use a remote telemonitoring system.

As telemedicine technology is improving continuously, participants expressed enthusiasm on the potential added value of telemedicine. Most participants were willing to incorporate technology as part of their diabetes management, but expressed the need to have sufficient training and on-going support, especially when they encountered issues such as equipment limitations. Our study also identified the potential benefits which fueled participants' enthusiasm towards telemedicine. These include receiving alerts, being able to respond to SMBG readings with advice from a

1
2
3 health care professional; as well as reducing opportunity cost incurred when using
4 telemedicine. Our study also offers an additional perspective and insight into the
5 importance of patient-provider relationship. Our results support previous research
6 which indicated that personal interaction with a health care practitioner was an
7 important aspect to support type 2 diabetes patients, especially when it involves
8 SMBG.^{14 31} This view was also expressed by most participants in the present study,
9 and also that a lack of emotional support especially when communicating through
10 remote telemonitoring resulted in participants dropping out of the study.
11
12
13
14
15
16
17
18
19
20
21
22

23
24 Our study also noted that not all participant perceived enhanced SMBG as a positive
25 tool to help achieve good glycaemic control. Some participants in this study expressed
26 reservation on the feedback and monitoring feature, which they felt intruded into their
27 personal space. They also expressed some tension between achieving good
28 glycaemic control and quality of life, especially with the involvement of health care
29 providers and family members, who they felt were acting as the “police”. As a result,
30 some of these patients opted not to take part in the randomized controlled trial, for fear
31 that this could further amplify the tension and strain in the relationship, an outcome
32 which they definitely did not want. Findings of this study identified several issues which
33 are salient in the literature. For example, our study like many others noted that patients
34 were acceptable to telemedicine due to its ability to reduce travel time³²⁻³⁴, increase
35 self-awareness^{35 36} and access to care^{37 38}. However, our study also found several
36 additional barriers that have never been reported in literature, such as the tensions
37 between operational practicality versus patient’s privacy and health security.

60

1
2
3
4
5 Our study offers several strength. By exploring the insights of patients, we illustrate
6 how family values and technology literacy could influence participants' opinion on
7 telemonitoring. Our study was also culturally specific to an Asian context and thus, we
8 could gain an in-depth understanding and broader views of participants' behaviors
9 when managing diabetes. There were some limitations to our study. Firstly, although
10 we had included a diverse sample of participants and reached thematic saturation in
11 our focus groups and in-depth interviews, these participants were only limited to one
12 geographical location in Malaysia. Participants in this current study were recruited
13 from suburban districts in Selangor where connectivity and technology literacy were
14 moderate. Future studies should include patients from both urban as well as rural
15 locations and those with high technology literacy, as this could potentially influence
16 the uptake and acceptability of telemedicine. While published literature suggests that
17 these trends are likely to be transferable to other regions in Malaysia, the context may
18 differ in other countries and settings. The views expressed here are solely from the
19 patients' point and does not represent the views of health care providers or policy
20 makers. Finally, our results cannot draw definitive conclusion regarding differences
21 in provider practices, patient knowledge as well as attitudes from different clinic sites
22 other than those examined in this study.

49
50

51 **Implications for practice**

52 The continual improvements in technology will facilitate the use of telemedicine in
53 the future. The largest implication will be its ability to reduce logistical barriers and
54 the potential to save time. However, it is important that any telemedicine programs
55
56
57
58
59
60

1
2
3 consider the economic standing and access to technology of patients, especially
4 those living in rural areas, who may have limited internet connectivity. As such,
5 health care professionals and policy makers need to take into consideration these
6 aspects prior to introducing any telemedicine technology for their patients to ensure
7 that patients' expectations are met. Another theme that emerged from this interview
8 was the need to invest in capacity building, especially in human resource.
9
10 Specifically, the creation of training programs, for both the general public as well as
11 health care workers, are particularly important, especially among the non-IT savvy
12 groups.

Conclusion

In conclusion, findings from this study indicate that the implementation of telemonitoring in diabetes management requires strategic planning with inputs from various stakeholders including, educators, health care providers, telco service providers and patients. The patient's personal and contextual factors, which could have a positive or negative effect on the uptake of the service should be taken into consideration. As such, health care providers need to discuss and consider patients' perspective to ensure the optimal use of telemedicine to improve patients' clinical parameters and quality of life.

This study was supported by the e-Science fund from the Ministry of Science, Technology and Innovation, Malaysia [03-02-10-SF0238 (MOSTI)], Telemedicine Cluster, Tropical Medicine and Biology platform, Monash University Malaysia (52140757-314-00) and SEGi University Research Fund (SEGi/2013/SKK/04/1).

Author Disclosure Statement

The authors report no conflict of interest.

Author Contributions

All authors named contributed substantially to the document. JYL conducted and transcribed the interview, interpreted the results and wrote the draft manuscript. SWHL obtained the funding, designed the study and provided support in editing the manuscript. CKYC, SSC, TP, KKCL, NHN and CSST contributed to the study design and critical review of the manuscript. All authors approved the final version.

Table 1: The interview guide topic areas and key questions

Topic area	Key questions used in interviews
Diabetes	<ul style="list-style-type: none"> • How would you describe your experience so far with diabetes? • How have you been coping with diabetes so far? Describe some of the ways you have been coping • Who and how much support do you have to cope with your conditions now • What are some of the most important treatment needs for a patient with diabetes
Telemedicine	<ul style="list-style-type: none"> • Describe and tell us your experience with using the web-enabled glucometer so far. • How do you think the system was able to affect your diabetes management? • How do you think other will accept this system? • What would you think are some areas where the system was good and where are the areas we can improve? • What do you think about using this system for the long term?

Table 2: Baseline demographics of participants who participated in the focus group

Patients (n= 48)	Men (n = 21)	Women (n = 27)
Age (years)	54.19	50.15
Range	29-62	31-69
Duration of diabetes (years)	4.06	6.88
Range	0.83-24	0.5-15
No. of oral hypoglycaemic agents used, n (%)		
1-2	18 (85)	27 (100)
≥3	1 (4)	0 (0)
No. of antihypertension drugs used, n (%)		
1-2	9 (42)	11 (40)
≥3	3 (14)	7 (25)
Insulin use, n (%)		
Yes	4 (19)	2 (7)
No	17 (81)	25 (93)

Data are expressed as mean, unless otherwise stated.

Box 1: IDEAS study

The Intervention for Diabetes with Education, Advancement and Support (IDEAS) study is a cluster randomized controlled study to evaluate the use of telemedicine to improve diabetes care. Participants in the telemedicine group were instructed to measure their blood glucose at least twice weekly (one fasting and one non-fasting) or more frequent as recommended by physician. These blood glucose readings will be transmitted via a Bluetooth technology to the participants' mobile phone to a remote secure server. Participants and their physicians were able to access the records on the server. Advice on lifestyle modification, any potential changes in medication, who and how to contact their healthcare providers were also given monthly during the study. A researcher also checked participants' results weekly and initiate intervention if needed (e.g. medication changes, counselling) with the consent of the attending physician.

Manuscript: Using telemedicine to support care for people with type 2 diabetes mellitus: A qualitative analysis of patient's perspective

Consolidated criteria for reporting qualitative studies (COREQ): 32-item checklist

Developed from:

Tong A, Sainsbury P, Craig J. Consolidated criteria for reporting qualitative research (COREQ): a 32-item checklist for interviews and focus groups. *International Journal for Quality in Health Care*. 2007. Volume 19, Number 6: pp. 349 – 357

No. Item	Guide questions/description	Reported on Page #
Domain 1: Research team and reflexivity		
<i>Personal Characteristics</i>		
1. Inter viewer/facilitator	Which author/s conducted the inter view or focus group?	9&10
2. Credentials	What were the researcher's credentials? E.g. PhD, MD	1
3. Occupation	What was their occupation at the time of the study?	1
4. Gender	Was the researcher male or female?	1
5. Experience and training	What experience or training did the researcher have?	9 & 10
<i>Relationship with participants</i>		
6. Relationship	Was a relationship established prior to study	10

1	established	commencement?	.
2			
3			
4			
5	7. Participant knowledge	What did the participants know about the	8
6	of the interviewer	researcher? e.g. personal goals, reasons for	
7		doing the research	
8			
9			
10	8. Interviewer	What characteristics were reported about the	9
11	characteristics	inter viewer/facilitator? e.g. Bias, assumptions,	
12		reasons and interests in the research topic

Domain 2: study design		
<i>Theoretical framework</i>		
9. Methodological orientation and Theory	What methodological orientation was stated to underpin the study? e.g. grounded theory, discourse analysis, ethnography, phenomenology, content analysis	9-10
<i>Participant selection</i>		
10. Sampling	How were participants selected? e.g. purposive, convenience, consecutive, snowball	8
11. Method of approach	How were participants approached? e.g. face-to-face, telephone, mail, email	8-9
12. Sample size	How many participants were in the study?	8
13. Non-participation	How many people refused to participate or dropped out? Reasons?	8
<i>Setting</i>		
14. Setting of data collection	Where was the data collected? e.g. home, clinic, workplace	9
15. Presence of non-participants	Was anyone else present besides the participants and researchers?	9
16. Description of sample	What are the important characteristics of the sample? e.g. demographic data, date	9-10
<i>Data collection</i>		

17. Interview guide	Were questions, prompts, guides provided by the authors? Was it pilot tested?	Table 1
18. Repeat interviews	Were repeat inter views carried out? If yes, how many?	No
19. Audio/visual recording	Did the research use audio or visual recording to collect the data?	9-10
20. Field notes	Were field notes made during and/or after the inter view or focus group?	No
21. Duration	What was the duration of the inter views or focus group?	10
22. Data saturation	Was data saturation discussed?	10
23. Transcripts returned	Were transcripts returned to participants for comment and/or correction?	No
Domain 3: analysis and findings		
<i>Data analysis</i>		
24. Number of data coders	How many data coders coded the data?	11
25. Description of the coding tree	Did authors provide a description of the coding tree?	11
26. Derivation of themes	Were themes identified in advance or derived from the data?	No
27. Software	What software, if applicable, was used to manage the data?	11
28. Participant checking	Did participants provide feedback on the findings?	12
<i>Reporting</i>		

29. Quotations presented	Were participant quotations presented to illustrate the themes/findings? Was each quotation identified? e.g. participant number	Yes. 13-19
30. Data and findings consistent	Was there consistency between the data presented and the findings?	20-23
31. Clarity of major themes	Were major themes clearly presented in the findings?	Yes. they were. 13-23
32. Clarity of minor themes	Is there a description of diverse cases or discussion of minor themes?	Discussion of major and minor themes 20-22

Standards for Reporting Qualitative Research (SRQR)*

<http://www.equator-network.org/reporting-guidelines/srqr/>

Page/line no(s).

Title and abstract

<p>Title - Concise description of the nature and topic of the study Identifying the study as qualitative or indicating the approach (e.g., ethnography, grounded theory) or data collection methods (e.g., interview, focus group) is recommended</p>	1
<p>Abstract - Summary of key elements of the study using the abstract format of the intended publication; typically includes background, purpose, methods, results, and conclusions</p>	3-4

Introduction

<p>Problem formulation - Description and significance of the problem/phenomenon studied; review of relevant theory and empirical work; problem statement</p>	6-7
<p>Purpose or research question - Purpose of the study and specific objectives or questions</p>	8

Methods

<p>Qualitative approach and research paradigm - Qualitative approach (e.g., ethnography, grounded theory, case study, phenomenology, narrative research) and guiding theory if appropriate; identifying the research paradigm (e.g., postpositivist, constructivist/ interpretivist) is also recommended; rationale**</p>	10
<p>Researcher characteristics and reflexivity - Researchers' characteristics that may influence the research, including personal attributes, qualifications/experience, relationship with participants, assumptions, and/or presuppositions; potential or actual interaction between researchers' characteristics and the research questions, approach, methods, results, and/or transferability</p>	10
<p>Context - Setting/site and salient contextual factors; rationale**</p>	9
<p>Sampling strategy - How and why research participants, documents, or events were selected; criteria for deciding when no further sampling was necessary (e.g., sampling saturation); rationale**</p>	9
<p>Ethical issues pertaining to human subjects - Documentation of approval by an appropriate ethics review board and participant consent, or explanation for lack thereof; other confidentiality and data security issues</p>	11
<p>Data collection methods - Types of data collected; details of data collection procedures including (as appropriate) start and stop dates of data collection and analysis, iterative process, triangulation of sources/methods, and modification of procedures in response to evolving study findings; rationale**</p>	9-10

1 2 3 4 5	Data collection instruments and technologies - Description of instruments (e.g., interview guides, questionnaires) and devices (e.g., audio recorders) used for data collection; if/how the instrument(s) changed over the course of the study	10-11 & Table 1
6 7 8	Units of study - Number and relevant characteristics of participants, documents, or events included in the study; level of participation (could be reported in results)	12
9 10 11 12	Data processing - Methods for processing data prior to and during analysis, including transcription, data entry, data management and security, verification of data integrity, data coding, and anonymization/de-identification of excerpts	10
13 14 15 16	Data analysis - Process by which inferences, themes, etc., were identified and developed, including the researchers involved in data analysis; usually references a specific paradigm or approach; rationale**	11
17 18 19 20	Techniques to enhance trustworthiness - Techniques to enhance trustworthiness and credibility of data analysis (e.g., member checking, audit trail, triangulation); rationale**	11

Results/findings

23 24 25 26	Synthesis and interpretation - Main findings (e.g., interpretations, inferences, and themes); might include development of a theory or model, or integration with prior research or theory	13-19
27 28 29	Links to empirical data - Evidence (e.g., quotes, field notes, text excerpts, photographs) to substantiate analytic findings	13-19

Discussion

32 33 34 35 36 37	Integration with prior work, implications, transferability, and contribution(s) to the field - Short summary of main findings; explanation of how findings and conclusions connect to, support, elaborate on, or challenge conclusions of earlier scholarship; discussion of scope of application/generalizability; identification of unique contribution(s) to scholarship in a discipline or field	20-22
38 39	Limitations - Trustworthiness and limitations of findings	22

Other

42 43 44	Conflicts of interest - Potential sources of influence or perceived influence on study conduct and conclusions; how these were managed	25
45 46	Funding - Sources of funding and other support; role of funders in data collection, interpretation, and reporting	25

*The authors created the SRQR by searching the literature to identify guidelines, reporting standards, and critical appraisal criteria for qualitative research; reviewing the reference lists of retrieved sources; and contacting experts to gain feedback. The SRQR aims to improve the transparency of all aspects of qualitative research by providing clear standards for reporting qualitative research.

Abstract

Objective: Telemedicine has been promoted as an economical and effective way to enhance patient care but its acceptability among patients in low and middle income countries is poorly understood. This study aimed to explore the experiences and perspectives of people with type 2 diabetes mellitus who used telemedicine to manage their condition.

Design: We conducted in-depth and focus group interviews with participants who used telemedicine. Questions included participants' perception on program use, satisfaction as well as engagement with the telemedicine program. All interviews and focus groups were audio-recorded and transcribed verbatim. Data were analyzed using a thematic approach.

Participants and setting: People with type 2 diabetes ($n=48$) who participated in a randomized controlled study which examined the using telemedicine for diabetes management.

Results: Twelve focus groups and two in-depth interviews were conducted. Four themes emerged from the analysis: (1) Generational difference; (2) Independence and convenience, (3) Sharing of health data and privacy; and (4) Concerns and challenges. The main barriers to using telemedicine were related to the user friendliness of the devices as well as internet connectivity. Cost was also another significant concern raised by participants. However, participants were generally positive about the benefits of telemedicine, including its ability to provide real time data and disease monitoring and the reduction in clinic visits.

Conclusion: Despite the potential positive benefits of using telemedicine for diabetes care, several barriers could inhibit the sustained and effective use of this technology.

1
2
3 As such, collaboration between educators, health care providers, telecommunication
4 service providers and patients is required to stimulate telemedicine adoption and use.

Strengths and limitations of this study

- Article followed the Standards for reporting qualitative Research (SRQR) recommendations on reporting
- Focus group discussion allowed the exchange of opinions about telemedicine, leading to richer information
- View and experiences of using telemedicine were captured from patients rather than that of healthcare providers
- The study was conducted in an urban setting in Malaysia and its applicability and transferability to other population remain unknown.

Introduction

Diabetes is a major health concern worldwide, and according to a recent report by the International Diabetes Federation, the global prevalence of diabetes will increase from 415 million in 2015 to 642 million in 2040.¹ The prevalence varies considerably between different regions, but the epicenter of the diabetes crisis is currently located in the Western Pacific and South-East Asia region, with 159 million and 82 million individuals with diabetes respectively.² In many individuals with diabetes, self-monitoring of blood glucose (SMBG) is considered as a key component of treatment, and widely recommended by clinical practice guidelines, irrespective of treatment strategy.³⁻⁷ SMBG is often used as an early warning sign for detecting hypoglycaemia, for improving the recognition of severe hyperglycaemia, to encourage physical activities as well as improve diet control. The data are also used by the treating physicians to facilitate an individualized treatment regimen.

Despite these potential benefits, there is controversy on the efficacy of SMBG, especially in non-insulin dependent type 2 diabetes, due to its cost, uncertainty on frequency of testing as well as impact on patients general health and well-being.⁸⁻¹⁰ Studies have shown that the use of enhanced SMBG (where there are high levels of engagement between patients and clinicians to interpret the SMBG values) has resulted in larger reduction in HbA1c compared to regular SMBG.^{4 11-13}

The application of telemedicine, or technology to deliver various aspects of health information, prevention, monitoring and medical care in diabetes management has been suggested as an innovative solution to improve diabetes care.¹⁴⁻¹⁶ Increasingly,

1
2
3 telemedicine is being viewed as a promising technology to assist patients in managing
4 diabetes,^{15 17 18} as it produces accurate and reliable data¹⁹, empowers patients¹⁴,
5
6 improves glycaemic control and influences their attitude and behaviours^{18 20},
7
8 potentially leading to a better quality of life.²¹ These telemedicine services can be
9
10 categorized to either synchronous (real-time), asynchronous (whereby data is stored
11
12 and forwarded subsequently) and continuous (remote monitoring). In diabetes care,
13
14 various forms of telemedicine services have been examined and include the use of
15
16 mobile phones, texting, emails, e-health portals, videoconferencing as well as remote
17
18 monitoring devices.
19
20
21
22
23
24
25

26 However, implementation of a telemedicine service in conventional care is a complex
27
28 process. While evidence has shown that telemedicine can expand the boundaries of
29
30 care to a larger population and offers person-centred care,²² examples of patients'
31
32 resistance to change exist.^{23 24} Nevertheless, one of the major limitations of existing
33
34 literature is the lack of studies which have examined the perspective of patients from
35
36 a low and middle income country, where telemedicine is now increasingly being used.
37
38 Earlier work on this topic have mostly focused on the views of physicians and few
39
40 studies have explored the patient's perspective.^{25 26} There was a limited understanding
41
42 on the drivers and barriers faced by patients using telemedicine; and most of these
43
44 studies have focused on the telemedicine technology as well as utilization rates of
45
46 telemedicine instead.^{24 27} Furthermore, very little is known as to how empirically
47
48 supported interventions can be transferred or implemented in resource-constraint
49
50 countries, i.e., in most developing countries. Understanding the behaviours among
51
52 various levels of stakeholders is an important component of successful
53
54 implementation research.²⁸

3
4
5
6
7
8 As patients' experience with telemedicine may be one of the reasons that will
9
10 determine the success or failure of any intervention, we conducted a qualitative study
11
12 to explore patients' views and experiences of telemedicine for diabetes management
13
14 in Malaysia. The study focused on the end users' perspective in context which were
15
16 necessary to ensure the successful delivery and implementation of a telemedicine
17
18 program for diabetes.

Materials and Methods

Study design

The present qualitative study was part of a larger multi-centre cluster randomized controlled study (IDEAS) conducted between April 2015 and June 2017, which aimed to examine the impact of a telemedicine program for people with type 2 diabetes (Box 1).^{29 30} This nested study design allowed the investigators to explore the facilitators and barriers to using telemedicine, as well as participants' view if telemedicine was implemented in routine practice.

Participants

Participants were recruited from eleven primary care clinics located within the Klang Valley, which is part of the Malaysian Ministry of Health's primary care clinic network. These clinics serve the districts of Klang and Petaling, which provides care for approximately 2.56 million individuals and can be considered to be nationally representative of primary care clinics in Malaysia.

In line with the qualitative nature of our study, we adopted a non-probability sampling approach, in which sampling was not guided by the idea of random selection or statistical representativeness. Nevertheless, we aimed to cover as broad a spectrum of participants who had experience using telemedicine, as possible. As such, we invited participants who had completed the IDEAS study to participate in the current qualitative study. Briefly, participants included those who: 1) had been diagnosed with

1
2
3 type 2 diabetes for at least 6 months; 2) aged between 18-75 years; 3) had regular
4 access to the Internet; 4) had HbA1c levels between 7.5% and 11.0%; and 5) were
5
6 randomized into the intervention arm of the IDEAS study^{29 30}. Participants were
7
8 excluded if they had no experience in using any telemedicine devices or had dropped
9
10 out of the IDEAS study. All potentially eligible participants were contacted by telephone
11
12 and invited to participate in the study. Participants were briefed regarding the purpose,
13
14 procedure and voluntary nature of the study and allowed to clarify their doubts.
15
16 Separate information sheet and written informed consent were obtained prior to
17
18 participation. To accommodate participants' schedules, all focus group interviews
19
20 were conducted at the respective health clinics, when participants visited the clinics
21
22 for their follow-up sessions with their physicians. In the event that a participant was
23
24 not able to attend a focus group session, an individual in-depth interview was
25
26 conducted at their own home. Study participants were incentivized with a RM50
27
28 (approximately USD\$12) voucher for their participation.

58
59
60

Interview schedule

42 A semi-structured interview was used in all the focus groups, which was based upon
43 an interview guide. Table 1 outlines the topic areas and key questions which were
44 used during the discussions. The topic guide aimed to capture the experiences of
45 patients in using telemedicine and was developed based on relevant literature.^{10 12 23}
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

54 The interviews were facilitated by the first author (JYL) and conducted either in Malay
55 or English language. Each interview lasted between 35 and 44 minutes in a private
56 room in the clinic. All interview sessions were digitally recorded, transcribed verbatim
57
58
59
60

1
2
3 immediately after each interview and checked for accuracy by SWHL. Interviews were
4
5 conducted to explore for emerging themes with simultaneous analysis of data until
6
7 data saturation was achieved, when no new themes or codes were identified.
8
9

10 11 12 **Data analysis**

13
14 The NVivo software version 11 (QSR International Pty Ltd) was used to organize and
15
16 code the data for thematic analysis, using both an inductive and deductive approach.³¹
17
18 All transcripts were read several times to familiarize with the data. Transcripts were
19
20 translated from Malay language to English by an independent research assistant. The
21
22 translated English transcripts were double checked by the first author (JYL) and any
23
24 discrepancies were resolved via discussion with another author (SWHL). Firstly,
25
26 transcripts were coded into an initial set of themes based on keywords or phrases that
27
28 appeared to convey an opinion or perception regarding telemedicine guided by
29
30 themes identified from previous literature^{10 12 23}. These initial codes were further
31
32 examined and refined, with codes combined to be main themes if they had similar
33
34 contexts or split into subthemes via an inductive process. The final codes were
35
36 summarized, cross checked and iteratively refined using paired analysis of transcripts
37
38 by two researchers (JYL and SWHL). In the event that there was a divergent
39
40 interpretation, the transcripts were reviewed again and discussed until consensus was
41
42 achieved.
43
44
45
46
47
48
49
50

51 **Ethics**

52
53 The study was approved by the Monash University Research Ethics Committee
54
55 (CF14/1977 – 2014001016 & CF15/1073 - 2015000502) and the National Medical
56
57 Research Register (NMRR-14-177-19466 & NMRR-14-1368-22943). All participants
58
59
60

1
2
3 provided written informed consent for participation in the research. This study was
4
5 registered with ClinicalTrials.gov under the registration NCT0246680.
6
7
8
9

10 **Patient and public involvement**

11
12 The current study was designed to understand patients views, perception and
13
14 experience of using telemedicine for type 2 diabetes management. Patients were not
15
16 involved in the initial design of the study, development of interview questions or
17
18 conduct of the study. All participants who participated in this qualitative study were
19
20 not provided with the results but were informed that the results will be published in a
21
22 peer-reviewed journal.

Results

Demographics of participants

A total of 48 participants were interviewed in the 12 focus group and 2 interview sessions. Each focus group had an average of between 3-4 participants, as we had difficulty arranging for larger groups due to different timing of clinic visits. The participants were mostly females (56.3%), with a mean age of 51.9 years, and have had diabetes for 5.6 years on average (Table 2). Four core themes emerged from the focus groups and the two in-depth interviews: (1) Generational difference (2) Independence and convenience, (3) Sharing of health data and privacy; and (4) Concerns and challenges.

Theme 1 – Generational differences

Our data suggest that there were generational differences with regards to participants' preference on how to record their blood glucose reading. Generally, older participants in this study (those aged 50 years and above) preferred to record their glucose readings manually, using pen and paper. They felt that the telemonitoring device required a lot of technical knowledge and was a challenging and complex process for them. As narrated by the participants:

“I (prefer to) manually record (my blood glucose readings). I do not understand (how to operate the mobile) telephone especially operating (the software). To me manual (recording) is easier.” [Patient 4, 59/F]

1
2
3 “But I am an old lady. I like it (blood glucose results) to be written (down). I'm
4 old (and) I need to write (the results) down. Anyway, as long as someone
5 shows me how to do it, I can do it. Of course (using telemedicine) is easier
6 because you bring your hand phone everywhere you go.” [Patient 5, 57/F]
7
8
9
10
11
12
13

14 These participants felt that the use of telemedicine was more suited for younger
15 individuals with diabetes who were more technology savvy. As explained by one
16 participant, “Maybe for the young ones. Technology (is) for youngsters (and) is more
17 suitable since they like to sit at home and like the thing called Internet.” [Patient 41,
18 67/M]
19
20
21
22
23
24
25
26
27

28 Some participants also expressed their preference to meet their health care providers
29 in person and reported that travelling to the clinic was not an onerous task.
30
31
32
33
34

35 “I don't mind coming to the clinic and have a chat with the doctor. We (can)
36 discuss (my medical condition) and sometimes we can ask questions and
37 doctors can show (my problem to me) physically. For me to use the Internet
38 is difficult to learn (as) my children are not here.” [Patient 6, 60/M]
39
40
41
42
43
44
45
46

47 Conversely, younger participants were more inclined to learn and use new
48 technologies if sufficient training and guidance were given. Additionally, they were
49 optimistic about using telemedicine to manage their conditions, as they knew the
50 various benefits that technology would provide, including data tracking ability and
51 convenience.
52
53
54
55
56
57
58
59
60

Theme 2 – Independence and convenience

Participants expressed that the use of a mobile phone which was connected to a glucometer was a convenient alternative to manage diabetes. Participants viewed it as a more convenient option in the event of time constraint or when they had issues commuting to the clinic for their appointment. Participants also mentioned that having a telemonitoring device encouraged them to monitor their glucose levels regularly compared to the quarterly check-ups at the clinic. As expressed by participants:

“It’s good to use especially over the Internet. It’s so much easier we do not have to come to the clinic and can stay at home” [Patient 12, 60/M].

“Digitals way (is the preferred choice). Everyday you can see (your blood glucose results) in the software so (there is) no need to record like manual. Sometimes even you record manual the paper will go wherever (or) missing. (Using) digital you have a backup.” [Patient 8, 35/F]

“I like this because you can transfer (your blood glucose results) directly to your phone. It’s useful to me as an indication. I prefer (using technology so) that I can use it to check how my medicine affects my glucose. I think that this is the best tools because you can monitor by the Internet everywhere you go.” [Patient 9, 44/M]

1
2
3 “It’s even more convenient since we do not have the time to come (to
4 the clinic) and sometimes some people do not have transport.” [Patient
5
6
7
8 10, 44/F]
9

10
11
12 Most participants were generally enthusiastic as they saw the potential benefits of
13 telemedicine. Participants described how the use of a web-based glucometer was
14
15 useful as it could provide them with reminders and alerts as well as the ability to
16
17 connect with their healthcare providers without going to the clinic. Nevertheless, they
18
19 expressed the desire and need to have more training and assistance, especially when
20
21 they had not used the device for some time, since they would have forgotten the
22
23 functions on the device.
24
25
26
27
28
29
30

31 “For me it’s not difficult ... just need to teach (me) that’s all. See the learning
32
33 condition first (and perhaps I need more training), maybe need two or three
34
35 times. I’m over fifty (years old) so (the) first time will be a problemneed
36
37 to teach a few times before I understand. First time might be difficult to
38
39 understand” [Patient 7, 56/M].
40
41
42
43
44
45
46
47
48

49 **Theme 3 – Sharing health data and privacy**

50
51
52

53 Our analysis showed that there were conflicting perspectives with data sharing.
54
55 Several participants expressed that they were willing to share their monitoring results
56
57 with family members, as they felt that the family member would make them
58
59
60

1
2
3 accountable for their diabetes management, which was a significant motivation for
4
5 them to meet their daily goals.
6
7
8
9

10 “The use of this what you call it (web-telemonitor)..... (I feel) my health
11
12 is better since my family members (also) monitor (my) sugar levels as
13
14 well” [Patient 11, 54/F].
15
16
17
18

19 “The good part (of telemedicine is) you can do it at home. If (you check
20
21 your blood glucose levels) at the clinic you get pricked (but) nobody
22
23 knows (the results)... but when you do it at home you children will be
24
25 informed as well” [Patient 5, 57/F].
26
27
28
29
30
31
32

33 Conversely, some participants expressed concern on the sharing of medical
34
35 information with their family members, which they felt their personal space was
36
37 infringed and could potentially lead to conflicts between family members.
38
39
40
41

42 “That thing (Telemonitoring device) is okay (to use) but what I am afraid of is
43
44 (that the use of telemonitoring may) sometimes (cause) conflicts because it
45
46 feels like you are being monitored by others. But it is beneficial, at least there
47
48 is somebody remind you” [Patient 1, 45/M].
49
50
51
52

53 Participants also expressed concern about the presence of malware in
54
55 telemonitoring devices that could compromise their personal information.
56
57
58
59
60

1
2
3 “(What happens when we have a) problem with the Internet (connection).
4
5 Occasionally we (may) receive the reading, but occasionally (we will be) unable
6
7 to (do so). (This can be) very inconvenient” [Patient 11, 54/F].
8
9

10
11
12
13
14
15 Some participants felt that meeting or contacting their health care providers was a
16
17 simpler and faster way to solve their queries as the health care practitioner would be
18
19 able to explain their clinical measures in a more concise manner. As explained by
20
21 one participant “Face-to face (consultation) is more important (as) its better. (With)
22
23 face-to face (consultation), information is clearer and more satisfying to me.” [Patient
24
25 2, 67F].
26
27
28
29

30 31 **Theme 4 – Concerns and challenges** 32

33
34
35 Participants in this study emphasized the importance of having a user-friendly
36
37 technology. Most participants in this study reported minor technical difficulties
38
39 especially with Internet connectivity and availability in rural areas, which limited their
40
41 ability to utilize the telemonitoring device effectively. Participants also expressed
42
43 concerns regarding the stability of Internet connection at their homes.
44
45
46
47
48

49 “I think depending on the situation.. whether you live in a village where (I feel)
50
51 it will be very difficult..... because (in) certain villages you don't have (Internet)
52
53 line so you (will) still need have (to record the blood glucose results) manually”
54
55 [Patient 8, 35/F].
56
57
58
59
60

1
2
3 Participants suggested the need to have a robust system which is user-friendly, with
4
5 good technical support which they felt were essential to ensure the successful
6
7 implementation of telemedicine.
8
9

10
11
12 “Okay but what happens when there is a virus? It is a problem for one week my
13
14 handphone “hang”. After one week it hangs (again)...that is a problem” [Patient
15
16 13, 54/F].
17
18

19
20
21 Another aspect which participants were worried of was the costs involved compared
22
23 to conventional care and that telemonitoring would only be suitable for affluent
24
25 patients.
26
27

28
29
30 “All this (telemedicine) is for people who are wealthy. Of course this is a good
31
32 system.” [Patient 14, 63/M]

Discussion

In our study, we present the conditions for the success of a telemonitoring health device for the management of managing type 2 diabetes, from the perspective of patients. We identified a set of distinctive but interrelated conditions which were and would be central to the success of such programs in the context of a developing country. Firstly, participants' demographic characteristics were crucial factors in ensuring the acceptability of telemedicine. We noted that younger participants between the ages of 29 and 50 years old preferred to use a web-based glucometer compared to older participants who preferred to record their results manually. Such outcome is not surprising, as younger individuals who grew up in this digital era were usually more technologically savvy compared to their older counterparts. This was noted in the IDEAS study where the average SMBG uploads were only 1 reading a week instead of the recommended 6 readings a week in the study.³⁰ Participants cited various reasons for being not being able to use a web-based glucometer. This included the lack of Internet connectivity especially in the rural areas. Concerns about the stability of Internet connections were the main barrier in using telemedicine in the management of diabetes in this study. The need for a simple, user friendly technology was also consistently highlighted, to encourage acceptability among participants on the use of a remote telemonitoring system.

As technology continues to advance, participants expressed enthusiasm on the potential added value of telemedicine. Potential benefits which ignited participants' enthusiasm towards telemedicine included the ability to receive alerts, access to SMBG readings with advice from a health care professional; as well as reduced

1
2
3 opportunity cost incurred. Most participants were willing to incorporate technology as
4 part of their diabetes management, but only if they were confident in using the device
5 or if they can seek help and support easily. Our study also offers an additional
6 perspective and insight into the importance of patient-provider relationship. Our results
7 support previous research which indicated that personal interaction with health care
8 practitioners was important to support people with type 2 diabetes, especially when it
9 involved SMBG.^{14 32} These views were also expressed by most participants in the
10 present study, and the lack of emotional support especially when communicating
11 through remote telemonitoring led to participants dropping out of the study.

22
23
24
25

26 Living with diabetes can be difficult, especially with the need to comply with a
27 demanding and often confusing set of self-care directives. Many individuals encounter
28 diabetes-related conflict with family members, which results in strained relationships.
29 As noted in this study, some participants expressed reservation on the feedback and
30 monitoring features of the telemonitoring device, as they felt that the device intruded
31 into their personal space, as well as gave them the feeling of being “watched”.
32 Consequently, some patients opted not to participate in the IDEAS²⁹ randomized
33 controlled trial. Findings of this study identified several issues which are salient in the
34 literature. For example, like many others noted that patients accepted telemedicine
35 due to its ability to reduce travel time³³⁻³⁵, increase self-awareness^{36 37} and increase
36 access to care^{38 39}.

46
47
48
49
50
51
52
53

54 The present study also found several additional barriers that have not been reported
55 in literature, such as tension between operational practicality versus patient’s privacy
56 and health security. As privacy and security risk may undermine the potential of
57
58
59
60

1
2
3 telemedicine, it is important that software developers consider this aspect as
4 information security is crucial to support a trusting relationship between patients and
5 providers. Therefore, collaboration with researchers in the field of security, especially
6 those specializing in network security and cryptography.

16

17 Our study offers several strengths. By exploring the insights of patients, we illustrate
18 how family values and technology literacy could influence participants' opinion on
19 telemonitoring. This method also allowed us to gain an in-depth understanding and
20 broader views of participants' behaviours when managing diabetes. Our study was
21 also culturally specific to an Asian context. There were some limitations to our study.
22 Firstly, although we had included a diverse sample of participants and reached
23 thematic saturation in our focus groups and in-depth interviews, these participants
24 were only limited to one geographical location in Malaysia. Participants in this current
25 study were recruited from suburban districts in Selangor where connectivity and
26 technology literacy were moderate. Future studies should include patients from both
27 urban as well as rural locations and among participants with high technology literacy,
28 as this could potentially influence the uptake and acceptability of telemedicine. While
29 published literature suggests that these trends are likely to be transferable to other
30 regions in Malaysia, the context may differ in other countries and settings. The views
31 expressed here are solely from the patients' point and does not represent the views of
32 health care providers or policy makers. Finally, our results cannot draw definitive
33 conclusion regarding differences in provider practices, patient knowledge as well as
34 attitudes from different clinic sites other than those examined in this study.

Implications for practice

The continual development and improvement in technology will facilitate the use of telemedicine in the future. The largest potential of telemedicine will be its ability to reduce logistical barriers and hence saves time. However, before any telemedicine programs are introduced, there is a need to consider the economic standing of patients and their access to technology. Those living in rural areas may have limited internet connectivity and hence efforts must be made to ensure that the expectations of patients are met. In addition, there is also a need to invest in capacity building, especially in human resource. Specifically, the creation of training programs on the functionalities of telemedicine for both the general public as well as health care workers, are particularly important, especially among the non-IT savvy groups.

Conclusion

Findings from this study indicate that the implementation of telemonitoring in diabetes management requires strategic planning with inputs from various stakeholders including, educators, health care providers, telco service providers and patients. The patient's personal and contextual factors, which could have a positive or negative effect on the uptake of the service should be taken into consideration. As such, health care providers need to discuss and consider the perspective of patients to ensure the optimal use of telemedicine to improve patients clinical parameters and quality of life.

Acknowledgements

The authors would like to thank all participants and health care providers who contributed their time to share their perspectives with us. We also wish to thank Drs Chirk Jenn Ng and Chee Piau Wong for helping to edit the article.

Funding source

This study was supported by the e-Science fund from the Ministry of Science, Technology and Innovation, Malaysia [03-02-10-SF0238 (MOSTI)], Telemedicine Cluster, Tropical Medicine and Biology platform, Monash University Malaysia (52140757-314-00) and SEGi University Research Fund (SEGi/2013/SKK/04/1).

Author Disclosure Statement

The authors report no conflict of interest.

Author Contributions

All authors named contributed substantially to the document. JYL conducted and transcribed the interview, interpreted the results and wrote the draft manuscript. SWHL obtained the funding, designed the study and provided support in editing the manuscript. CKYC, SSC, TP, KKCL, NHN and CSST contributed to the study design and critical review of the manuscript. All authors approved the final version.

Box 1: IDEAS study

The Intervention for Diabetes with Education, Advancement and Support (IDEAS) study is a cluster randomized controlled study to evaluate the use of telemedicine to improve diabetes care. Participants in the telemedicine group were instructed to measure their blood glucose at least twice weekly (one fasting and one non-fasting) or more frequent as recommended by physician. These blood glucose readings will be transmitted via a Bluetooth technology to the participants' mobile phone to a remote secure server. Participants and their physicians were able to access the records on the server. Advice on lifestyle modification, any potential changes in medication, who and how to contact their healthcare providers were also given monthly during the study. A researcher also checked participants' results weekly and initiate intervention if needed (e.g. medication changes, counselling) with the consent of the attending physician.

Standards for Reporting Qualitative Research (SRQR)*

<http://www.equator-network.org/reporting-guidelines/srqr/>

Page/line no(s).

Title and abstract

<p>Title - Concise description of the nature and topic of the study Identifying the study as qualitative or indicating the approach (e.g., ethnography, grounded theory) or data collection methods (e.g., interview, focus group) is recommended</p>	1
<p>Abstract - Summary of key elements of the study using the abstract format of the intended publication; typically includes background, purpose, methods, results, and conclusions</p>	3-4

Introduction

<p>Problem formulation - Description and significance of the problem/phenomenon studied; review of relevant theory and empirical work; problem statement</p>	6-7
<p>Purpose or research question - Purpose of the study and specific objectives or questions</p>	8

Methods

<p>Qualitative approach and research paradigm - Qualitative approach (e.g., ethnography, grounded theory, case study, phenomenology, narrative research) and guiding theory if appropriate; identifying the research paradigm (e.g., postpositivist, constructivist/ interpretivist) is also recommended; rationale**</p>	10
<p>Researcher characteristics and reflexivity - Researchers' characteristics that may influence the research, including personal attributes, qualifications/experience, relationship with participants, assumptions, and/or presuppositions; potential or actual interaction between researchers' characteristics and the research questions, approach, methods, results, and/or transferability</p>	10
<p>Context - Setting/site and salient contextual factors; rationale**</p>	9
<p>Sampling strategy - How and why research participants, documents, or events were selected; criteria for deciding when no further sampling was necessary (e.g., sampling saturation); rationale**</p>	9
<p>Ethical issues pertaining to human subjects - Documentation of approval by an appropriate ethics review board and participant consent, or explanation for lack thereof; other confidentiality and data security issues</p>	11
<p>Data collection methods - Types of data collected; details of data collection procedures including (as appropriate) start and stop dates of data collection and analysis, iterative process, triangulation of sources/methods, and modification of procedures in response to evolving study findings; rationale**</p>	9-10

1 2 3 4 5	Data collection instruments and technologies - Description of instruments (e.g., interview guides, questionnaires) and devices (e.g., audio recorders) used for data collection; if/how the instrument(s) changed over the course of the study	10-11 & Table 1
6 7 8	Units of study - Number and relevant characteristics of participants, documents, or events included in the study; level of participation (could be reported in results)	12
9 10 11 12	Data processing - Methods for processing data prior to and during analysis, including transcription, data entry, data management and security, verification of data integrity, data coding, and anonymization/de-identification of excerpts	10
13 14 15 16	Data analysis - Process by which inferences, themes, etc., were identified and developed, including the researchers involved in data analysis; usually references a specific paradigm or approach; rationale**	11
17 18 19 20	Techniques to enhance trustworthiness - Techniques to enhance trustworthiness and credibility of data analysis (e.g., member checking, audit trail, triangulation); rationale**	11

Results/findings

23 24 25 26	Synthesis and interpretation - Main findings (e.g., interpretations, inferences, and themes); might include development of a theory or model, or integration with prior research or theory	13-19
27 28 29	Links to empirical data - Evidence (e.g., quotes, field notes, text excerpts, photographs) to substantiate analytic findings	13-19

Discussion

32 33 34 35 36 37	Integration with prior work, implications, transferability, and contribution(s) to the field - Short summary of main findings; explanation of how findings and conclusions connect to, support, elaborate on, or challenge conclusions of earlier scholarship; discussion of scope of application/generalizability; identification of unique contribution(s) to scholarship in a discipline or field	20-22
38 39	Limitations - Trustworthiness and limitations of findings	22

Other

42 43 44	Conflicts of interest - Potential sources of influence or perceived influence on study conduct and conclusions; how these were managed	25
45 46	Funding - Sources of funding and other support; role of funders in data collection, interpretation, and reporting	25

*The authors created the SRQR by searching the literature to identify guidelines, reporting standards, and critical appraisal criteria for qualitative research; reviewing the reference lists of retrieved sources; and contacting experts to gain feedback. The SRQR aims to improve the transparency of all aspects of qualitative research by providing clear standards for reporting qualitative research.

Abstract

Objective: Telemedicine has been promoted as an economical and effective way to enhance patient care, but its acceptance among patients in low and middle income countries is poorly understood. This study is aimed to explore the experiences and perspectives of people with type 2 diabetes mellitus that used telemedicine to manage their condition.

Design: In-depth and focus group interviews were conducted with participants who have engaged in telemedicine. Questions included were participants' perception on the programme being used, satisfaction as well as engagement with the telemedicine programme. All interviews and focus groups were audio-recorded and transcribed verbatim. Data were analyzed using a thematic approach.

Participants and setting: People with type 2 diabetes ($n=48$) who participated in a randomized controlled study which examined the use of telemedicine for diabetes management were recruited from eleven primary care clinics located within the Klang Valley.

Results: Twelve focus groups and two in-depth interviews were conducted. Four themes emerged from the analysis: (1) Generational difference; (2) Independence and convenience, (3) Sharing of health data and privacy; and (4) Concerns and challenges. The main obstacles found in patients using the telemedicine systems were related to internet connectivity and difficulties experienced with system interface. Cost was also another significant concern raised by participants. Participants in this study were primarily positive about the benefits of telemedicine, including its ability to provide real time data and disease monitoring and the reduction in clinic visits.

1
2
3 **Conclusion:** Despite the potential benefits of telemedicine in the long term care of
4 diabetes, there are several perceived barriers that may limit the effectiveness of this
5 technology. As such, collaboration between educators, health care providers,
6 telecommunication service providers and patients are required to stimulate the
7 adoption and the use of telemedicine.

Strengths and limitations of this study

- The study followed the Standards for Reporting Qualitative Research (SRQR) recommendations
- Focus group discussion allowed for the exchange of opinions relating to the use of telemedicine
- The views and experiences with telemedicine were documented from the patients' perspectives instead of the healthcare providers' perspective
- The study was conducted in an urban setting in Malaysia. The implications related to other populations is unknown.

Introduction

Diabetes is a major health concern worldwide with a global prevalence of 415 million in 2015 rising to 642 million in 2040.¹ The prevalence of diabetes varies considerably between different global regions, but the epicentre of the disease is currently in the Western Pacific and South-East Asia regions, with 159 million and 82 million individuals with diabetes respectively.² Self-monitoring of blood glucose (SMBG) is considered to be a key component in the treatment of diabetes, and is widely recommended in clinical practice guidelines, irrespective of subsequent treatment strategy.³⁻⁷ SMBG is often used as an early indicator for detecting hypoglycaemia, monitoring severe hyperglycaemia and encouraging physical activity as well as improving diet control. The long term individualised patient data are often used to inform treatment regimens.⁸

Despite these potential benefits, there is controversy regarding the efficacy of SMBG, especially in non-insulin dependent type 2 diabetes, due to its cost, uncertainty with frequency of testing as well as the impact on patient's general health and well-being.⁹⁻¹¹ Studies have shown that the use of enhanced SMBG (where there are high levels of engagement between patients and clinicians when interpreting a patient's SMBG values) has resulted in better maintenance of glycated haemoglobin (HbA1c) levels when compared to regular SMBG.^{4 12-14}

The application of telemedicine in delivering various aspects of health information, from the information on the prevention of disease, to the monitoring of medical conditions as well as regular medical care for diabetes management has been

1
2
3 suggested as an innovative solution to improve diabetic patient care.¹⁵⁻¹⁷ Telemedicine
4 is being viewed as a useful tool to assist patients in managing diabetes,^{16 18 19} as it
5 facilitates the communication of accurate and reliable data²⁰ between patients and
6 their healthcare providers. It also empowers patients¹⁵ attitude and behavior^{19 21}
7 towards a healthier lifestyle while providing them with an outlook for better glycaemic
8 control.²² These telemedicine services can be categorized into either synchronous
9 (real-time), asynchronous (whereby data is stored and forwarded subsequently) and
10 continuous (remote monitoring). In diabetes care, various forms of telemedicine
11 services have been examined. These include the use of mobile phones, text
12 messages, email, e-health portals, videoconferences as well as remote monitoring
13 devices.

31 Implementation of a telemedicine service in conventional care is a complex process.
32 While evidence has shown that telemedicine may expand the boundaries of
33 healthcare to a larger population and may offer person-centred care,²³ there are still
34 examples where patients' resist these changes.^{24 25} One of the major limitations of
35 existing literature is the lack of studies which have examined the perspectives of
36 patients in low to middle income countries such as Malaysia, where telemedicine is
37 now being used. Earlier published work on this topic has focused primarily on the
38 views of physicians rather than the patient's perspective.^{26 27} There was a limited
39 understanding of the key factors faced by patients using telemedicine as most of these
40 studies have focused primarily on its utilization rates.^{25 28} Furthermore, very little is
41 known as to how empirically supported interventions can be transferred or
42 implemented in resource-constrained countries, i.e., in most developing countries.

10

11
12 As patients' experience with telemedicine may be a major reason in determining the
13
14 uptake of this system, we conducted a qualitative study to explore patients' views and
15
16 experiences of telemedicine for diabetes management in Malaysia. The study focused
17
18 on the patient's ' perspective in context which was necessary to ensure the successful
19
20 delivery and implementation of a telemedicine programme for diabetes.

Materials and Methods

Study design

The present qualitative study was part of a larger multi-centre cluster randomized controlled study (IDEAS) conducted between April 2015 and June 2017, which examined the impact of a telemedicine programme for people with type 2 diabetes (Box 1).^{30 31} This nested study design allowed the investigators to explore the perceived obstacles and incentives patients experienced when using telemedicine in the management of their type 2 diabetes.

Participants and Setting

Participants were recruited from 11 primary care clinics located within the Klang Valley, which is part of the Malaysian Ministry of Health's primary care clinic network. These clinics serve the districts of Klang and Petaling, which provide care for approximately 2.56 million individuals. These individuals are considered to be representative of primary care clinics in Malaysia.

This qualitative study adopted a non-probability sampling method, where sampling was not guided by the idea of random selection or statistical representation. Nevertheless, we aimed to cover as broad a spectrum of participants who had experienced using telemedicine. We invited participants who had completed the IDEAS study to participate in the current qualitative study. Participants included those who: 1) had been diagnosed with type 2 diabetes for at least 6 months; 2) aged

1
2
3 between 18-75 years; 3) had regular access to the Internet; 4) had HbA1c levels
4
5 between 7.5% and 11.0%; and 5) were randomized into the intervention arm of the
6
7 IDEAS study^{30 31}. Participants were excluded if they had no experience in using
8
9 telemedicine devices or had dropped out of the IDEAS study³¹. All potentially eligible
10
11 participants were contacted by telephone and invited to participate in the study.
12
13 Participants were briefed on the purpose, procedure and voluntary nature of the study
14
15 and were allowed to clarify their concerns. A separate information sheet was given to
16
17 the participants and written informed consent was obtained prior to the start of the
18
19 study. To accommodate participants' schedules, all focus group interviews were
20
21 conducted when participants visited the clinics for their follow-up sessions (at weeks
22
23 4, 12, 24 or 48) with their physicians. In the event a participant was not able to attend a
24
25 focus group session, an individual in-depth interview was conducted at their home.
26
27 Study participants were given a RM50 (approximately USD\$12) voucher for their
28
29 participation.
30
31
32
33
34
35
36
37

38 **Interview schedule**

39
40
41
42 A semi-structured interview was used in all the focus groups, and this was based on
43
44 the topic areas and key questions outlined in Table 1. The topic guide aimed to capture
45
46 the experiences of patients in using telemedicine and was developed based on
47
48 relevant literature.^{11 13 24}
49
50
51
52

53
54 The interviews were facilitated by the first author (JYL) and conducted either in Malay
55
56 or English. Each interview lasted between 35 and 44 minutes in a private room in the
57
58 clinic. All interview sessions were digitally recorded, transcribed verbatim immediately
59
60

1
2
3 after each interview and checked for accuracy by SWHL. Interviews were conducted
4
5 to explore for emerging themes with simultaneous analysis of data until data saturation
6
7 was achieved, when no new themes or codes were identified.
8
9

10 11 12 **Data analysis**

13
14 The NVivo software version 11 (QSR International Pty Ltd) was used to organize and
15
16 code the data for thematic analysis, using both an inductive and deductive approach.³²
17
18 All transcripts were read several times to familiarize with the data. Transcripts were
19
20 translated from Malay language to English by an independent research assistant. The
21
22 translated English transcripts were double checked by the first author (JYL) and any
23
24 discrepancies were resolved via discussion with another author (SWHL). Firstly,
25
26 transcripts were coded into an initial set of themes based on keywords or phrases that
27
28 appeared to convey an opinion or perception regarding telemedicine guided by
29
30 themes identified from previous literature^{11 13 24}. These initial codes were further
31
32 examined and refined, with codes combined to be main themes if they had similar
33
34 contexts or split into subthemes via an inductive process. The final codes were
35
36 summarized, cross checked and iteratively refined using paired analysis of transcripts
37
38 by two researchers (JYL and SWHL). In the event that there was a divergent
39
40 interpretation, the transcripts were reviewed again and discussed until consensus was
41
42 achieved.
43
44
45
46
47
48
49
50

51 **Ethics**

52
53 The study was approved by the Monash University Research Ethics Committee
54
55 (CF14/1977 – 2014001016 & CF15/1073 - 2015000502) and the National Medical
56
57 Research Register (NMRR-14-177-19466 & NMRR-14-1368-22943). All participants
58
59
60

1
2
3 provided written informed consent for participation in the research. This study was
4
5 registered with ClinicalTrials.gov under the registration NCT0246680.
6
7
8
9

10 **Patient and public involvement**

11
12 The current study was designed to understand patients' views, perceptions and
13
14 experiences in using telemedicine for type 2 diabetes management. Patients were
15
16 not involved in the initial design of the study, development of interview questions or
17
18 conduct of the study. All participants in this qualitative study were not provided with
19
20 the results but were informed that the results will be published in a peer-reviewed
21
22 journal.

Results

Demographics of participants

A total of 48 participants were interviewed in 12 focus group and two interview sessions. Each focus group had an average of between 3-4 participants, as we had difficulty arranging for larger groups due to different timing of clinic visits. The participants were mostly females (56.3%), with a mean age of 51.9 years, and have had diabetes for 5.6 years on average (Table 2). Four core themes emerged from the focus groups and the two in-depth interviews: (1) Generational difference (2) Independence and convenience, (3) Sharing of health data and privacy; and (4) Concerns and challenges.

Theme 1 – Generational differences

Our data suggests that there were generational differences with regards to participants' preference on how to record their blood glucose reading. Generally, older participants in this study (those aged 50 years and above) preferred to record their glucose readings manually, using pen and paper. They felt that the telemonitoring device required technical knowledge and was a challenging and complex process for them. As narrated by the participants:

“I (prefer to) manually record (my blood glucose readings). I do not understand (how to operate the mobile) telephone especially operating (the software). To me manual (recording) is easier.” [Patient 4, 59/F]

1
2
3 “But I am an old lady. I like it (blood glucose results) to be written (down). I'm
4 old (and) I need to write (the results) down. Anyway, as long as someone
5 shows me how to do it, I can do it. Of course (using telemedicine) is easier
6 because you bring your hand phone everywhere you go.” [Patient 5, 57/F]
7
8
9
10
11
12
13

14 These participants felt that the use of telemedicine was more suited for younger
15 individuals with diabetes who were more familiar with technology utilisation. As
16 explained by one participant, “Maybe for the young ones. Technology (is) for
17 youngsters (and) is more suitable since they like to sit at home and like the thing called
18 Internet.” [Patient 41, 67/M]
19
20
21
22
23
24
25
26
27

28 Some participants also expressed their preference to meet their health care providers
29 in person and reported that travelling to the clinic was preferred.
30
31
32
33
34

35 “I don't mind coming to the clinic and have a chat with the doctor. We (can)
36 discuss (my medical condition) and sometimes we can ask questions and
37 doctors can show (my problem to me) physically. For me to use the Internet
38 is difficult to learn (as) my children are not here.” [Patient 6, 60/M]
39
40
41
42
43
44
45
46

47 Conversely, younger participants were more inclined to learn and use new
48 technologies if sufficient training and guidance were given. Additionally, they were
49 optimistic about using telemedicine to manage their conditions, as they knew the
50 various benefits that technology would provide, including the data analytics ability and
51 convenience.

Theme 2 – Independence and convenience

Participants expressed that the use of a mobile phone connected to a glucometer was a convenient method that contributed to the improved management of their diabetes. Participants considered this to be a convenience when time constraints or logistical issues prevented them from attending the clinic for their appointment. Participants also mentioned that having a telemonitoring device encouraged them to monitor their glucose levels regularly compared to the quarterly check-ups at the clinic. As expressed by participants:

“It’s good to use especially over the Internet. It’s so much easier we do not have to come to the clinic and can stay at home” [Patient 12, 60/M].

“Digital way (is the preferred choice). Everyday you can see (your blood glucose results) in the software so (there is) no need to record like manual. Sometimes even you record manual the paper will go wherever (or) missing. (Using) digital you have a backup.” [Patient 8, 35/F]

“I like this because you can transfer (your blood glucose results) directly to your phone. It’s useful to me as an indication. I prefer (using technology so) that I can use it to check how my medicine affects my glucose. I think that this is the best tools because you can monitor by the Internet everywhere you go.” [Patient 9, 44/M]

1
2
3 “It’s even more convenient since we do not have the time to come (to
4 the clinic) and sometimes some people do not have transport.” [Patient
5
6
7
8 10, 44/F]
9

10
11
12 Most participants were generally enthusiastic as they saw the potential benefits of
13 telemedicine. Participants described how the use of a web-based glucometer was
14 useful as it could provide them with reminders and alerts as well as the ability to
15 connect with their healthcare providers without going to the clinic. Nevertheless, they
16 expressed the desire and need to have more training and assistance, especially when
17 they had not used the device for some time, since they would have forgotten the
18 functions on the device.
19
20
21
22
23
24
25
26
27
28
29

30
31 “For me it’s not difficult ... just need to teach (me) that’s all. See the learning
32 condition first (and perhaps I need more training), maybe need two or three
33 times. I’m over fifty (years old) so (the) first time will be a problemneed
34 to teach a few times before I understand. First time might be difficult to
35 understand” [Patient 7, 56/M].
36
37
38
39
40
41
42
43
44
45
46
47
48

49 **Theme 3 – Sharing health data and privacy**

50
51
52

53 Our analysis showed that there were conflicting perspectives with data sharing.
54
55 Several participants expressed that they were willing to share their monitoring results
56
57
58
59
60

1
2
3 with family members, as they felt accountable for their diabetes management, which
4
5 was a significant motivation for them to meet their daily goals.
6
7
8
9

10 “The use of this what you call it (web-telemonitor)..... (I feel) my health
11
12 is better since my family members (also) monitor (my) sugar levels as
13
14 well” [Patient 11, 54/F].
15
16
17
18

19 “The good part (of telemedicine is) you can do it at home. If (you check
20
21 your blood glucose levels) at the clinic you get pricked (but) nobody
22
23 knows (the results)... but when you do it at home you children will be
24
25 informed as well” [Patient 5, 57/F].
26
27
28
29
30
31
32

33 Conversely, some participants expressed concern with the sharing of medical
34
35 information with their family members, whereby they felt that their privacy was
36
37 infringed and could potentially lead to conflicts between family members.
38
39
40
41

42 “That thing (Telemonitoring device) is okay (to use) but what I am afraid of is
43
44 (that the use of telemonitoring may) sometimes (cause) conflicts because it
45
46 feels like you are being monitored by others. But it is beneficial, at least there
47
48 is somebody remind you” [Patient 1, 45/M].
49
50
51
52

53 Participants also expressed concern about the presence of malware in
54
55 telemonitoring devices that could compromise their personal information.
56
57
58
59
60

1
2
3 “(What happens when we have a) problem with the Internet (connection).
4
5 Occasionally we (may) receive the reading, but occasionally (we will be) unable
6
7 to (do so). (This can be) very inconvenient” [Patient 11, 54/F].
8
9

10
11
12
13
14
15 Some participants felt that meeting or contacting their health care providers was a
16
17 simpler and faster way to solve their queries as the health care practitioner would be
18
19 able to explain their clinical measures in a more concise manner. As explained by
20
21 one participant “Face-to face (consultation) is more important (as) its better. (With)
22
23 face-to face (consultation), information is clearer and more satisfying to me.” [Patient
24
25 2, 67F].
26
27
28
29

30 **Theme 4 – Concerns and challenges**

31
32
33
34
35 Participants in this study emphasized the importance of having a user-friendly
36
37 technology. Most participants in this study reported minor technical difficulties
38
39 especially with internet connectivity and availability in rural areas, which limited their
40
41 ability to utilize the telemonitoring device effectively. Participants also expressed
42
43 concerns regarding the stability of internet connection at their homes.
44
45
46
47
48

49 “I think depending on the situation.. whether you live in a village where (I feel)
50
51 it will be very difficult..... because (in) certain villages you don't have (Internet)
52
53 line so you (will) still need have (to record the blood glucose results) manually”
54
55 [Patient 8, 35/F].
56
57
58
59
60

1
2
3 Participants suggested the need to have a robust system which is user-friendly, with
4
5 good technical support which they felt were essential to ensure the successful
6
7 implementation of telemedicine.
8
9

10
11
12 “Okay but what happens when there is a virus? It is a problem for one week my
13
14 handphone “hang”. After one week it hangs (again)...that is a problem” [Patient
15
16 13, 54/F].
17
18

19
20
21 Another aspect which participants were worried of was the costs involved compared
22
23 to conventional care and that telemonitoring would only be suitable for affluent
24
25 patients.
26
27

28
29
30 “All this (telemedicine) is for people who are wealthy. Of course this is a good
31
32 system.” [Patient 14, 63/M]

Discussion

In our study, we present the conditions in the success of a telemonitoring health device for managing type 2 diabetes from the perspectives of patients. We identified a set of distinctive but interrelated conditions which were and would be central to the success of such programmes in the context of a developing country. Firstly, participants' age were crucial in ensuring the success of telemedicine. We noted that younger participants between the ages of 29 and 50 years old preferred to use a web-based glucometer compared to older participants (aged 50 and above) who preferred to record their results manually. This outcome is not surprising, as younger individuals are more familiar with technology and its use. This was noted in the IDEAS study where the average SMBG uploads were only one reading per week instead of the recommended six readings a week.³¹ Participants cited various reasons for being not being able to use a web-based glucometer. These included the lack of internet connectivity especially in the rural areas. Concerns about the stability of internet connections were the main barrier in using telemedicine in the management of diabetes in this study. The need for a simple, user friendly technology was also consistently highlighted in order to encourage acceptance and adoption among participants on the use of a remote telemonitoring system.

Participants expressed enthusiasm with the potential added value of telemedicine with to their medical conditions. The perceived benefits of telemedicine included the ability to receive alerts, access to SMBG readings with advice from a health care professional; as well as reduced cost on their treatments. Most participants were willing to incorporate technology as part of their diabetes management, but only if they

1
2
3 were confident in using the device or if they could seek help and support easily. Our
4
5 results support previous research which indicated that personal interaction with health
6
7 care practitioners was important to support people with type 2 diabetes, especially
8
9 when it involved SMBG.^{15 33} These views were also expressed by most participants in
10
11 the present study, and the lack of clinical support especially when communicating
12
13 through remote telemonitoring led to participants dropping out of the study.
14
15
16
17
18

19 Living with diabetes can be difficult, especially with the need to comply with a
20
21 demanding and often confusing set of self-care directives. Many individuals encounter
22
23 diabetes-related conflicts with family members, which results in strained relationships.
24
25 As noted in this study, some participants expressed reservation on the feedback and
26
27 monitoring features of the telemonitoring device, as they felt that the device intruded
28
29 into their privacy, as well as gave them the feeling of being “watched”. Consequently,
30
31 some patients opted not to participate in the IDEAS³⁰ randomized controlled trial. The
32
33 findings of this study identified several salient issues which are reflected in the
34
35 literature. For example, many others noted that patients accepted telemedicine due to
36
37 its ability to reduce travel time³⁴⁻³⁶, increase self-awareness^{37 38} and increase access
38
39 to care^{39 40}.
40
41
42
43
44
45
46

47 The present study also found several additional barriers that have not been reported
48
49 in previous literature, such as conflict between operational practicality versus patient’s
50
51 privacy and healthcare data security. As privacy and security risk may undermine the
52
53 potential of telemedicine, it is important that software developers must consider this
54
55 aspect as information security is crucial to support a trusting relationship between
56
57 patients and providers. Therefore, collaboration with researchers in the field of
58
59
60

1
2
3 cybersecurity, especially those specializing in network security and cryptography is
4
5 necessary.
6
7
8
9
10

11
12 Our study offers several strengths. By exploring the insights of patients, we illustrate
13 how family values and technology literacy could influence participants' opinions on the
14 use of telemonitoring in their medical condition. This method also allowed us to gain
15 an in-depth understanding and broader views of participants' behaviour when
16 managing diabetes. Our study was also culturally specific in an Asian context.
17
18
19
20
21
22
23
24
25
26
27

28 There were some limitations to our study. Firstly, although we included a diverse
29 sample of participants and reached thematic saturation in our focus groups and in-
30 depth interviews, these participants were only limited to one geographical location in
31 Malaysia. Participants in this current study were recruited from suburban districts in
32 Selangor where connectivity and technology literacy were moderate. Future studies
33 should include patients from both urban and rural locations and also include
34 participants with high technology literacy, as this could potentially influence the uptake
35 and acceptability of telemedicine. While published literature suggests that these trends
36 are likely to be transferable to other regions in Malaysia, the context may differ in other
37 countries and settings. The views expressed here are solely from the patients' and
38 do not represent the views of health care providers or policymakers. Finally, our
39 results cannot draw a definitive conclusion regarding differences in provider practices,
40 patient knowledge as well as attitudes from different clinic sites other than those
41 examined in this study.

Implications for practice

The continued development and improvement in healthcare technology will hopefully facilitate the use of telemedicine in the future. The largest potential use of telemedicine will be its ability to reduce logistical barriers and hence save time. However, before any telemedicine programs are introduced, there is a need to consider the economic standing of patients and their access to technology. Those living in rural areas may have limited internet connectivity and hence efforts must be made to ensure that the expectations of patients are met. Also, there is a need to invest in capacity building, especially in human resource. Specifically, the creation of training programs on the use of telemedicine for both the general public and health care workers, are particularly important, especially among the non-IT competent groups of users.

Conclusion

Results from this study indicate that the implementation of telemonitoring in diabetes management requires strategic planning with input from various stakeholders including, educators, health care providers, telecom service providers and patients. The patient's personal and contextual factors, which could have a positive or negative effect on the uptake of the service should be taken into consideration. As such, health care providers need to discuss and consider the perspective of their patients to ensure the optimal use of telemedicine to improve patients' clinical parameters and quality of life.

Acknowledgements

The authors would like to thank all participants and health care providers who contributed their time to share their perspectives with us. We also wish to thank Drs Chirk Jenn Ng and Chee Piau Wong for helping to edit the article, Chan Yan Yew from USA and Dr Alan Worsley from Hong Kong University for helping with the English edits of this manuscript

Funding source

This study was supported by the e-Science fund from the Ministry of Science, Technology and Innovation, Malaysia [03-02-10-SF0238 (MOSTI)], Telemedicine Cluster, Tropical Medicine and Biology platform, Monash University Malaysia (52140757-314-00) and SEGi University Research Fund (SEGi/2013/SKK/04/1).

Table 1: The interview guide topic areas and key questions

Topic area	Key questions used in interviews
Diabetes	<ul style="list-style-type: none"> • How would you describe your experience so far with diabetes? • How have you been coping with diabetes so far? Describe some of the ways you have been coping • Who and how much support do you have to cope with your conditions now • What are some of the most important treatment needs for a patient with diabetes
Telemedicine	<ul style="list-style-type: none"> • Describe and tell us your experience with using the web-enabled glucometer so far. • How do you think the system was able to affect your diabetes management? • How do you think other will accept this system? • What would you think are some areas where the system was good and where are the areas we can improve? • What do you think about using this system for the long term?

Table 2: Baseline demographics of participants who participated in the focus group

Patients (n= 48)	Men (n = 21)	Women (n = 27)
Age (years)	54.19	50.15
Range	29-62	31-69
Duration of diabetes (years)	4.06	6.88
Range	0.83-24	0.5-15
No. of oral hypoglycaemic agents used, n (%)		
1-2	18 (85)	27 (100)
≥3	1 (4)	0 (0)
No. of antihypertension drugs used, n (%)		
1-2	9 (42)	11 (40)
≥3	3 (14)	7 (25)
Insulin use, n (%)		
Yes	4 (19)	2 (7)
No	17 (81)	25 (93)

Data are expressed as mean, unless otherwise stated.

Box 1: IDEAS study

The Intervention for Diabetes with Education, Advancement and Support (IDEAS) study is a cluster randomized controlled study to evaluate the use of telemedicine to improve diabetes care. Participants in the telemedicine group were instructed to measure their blood glucose at least twice weekly (one fasting and one non-fasting) or more frequent as recommended by physician. These blood glucose readings will be transmitted via a Bluetooth technology to the participants' mobile phone to a remote secure server. Participants and their physicians were able to access the records on the server. Advice on lifestyle modification, any potential changes in medication, who and how to contact their healthcare providers were also given monthly during the study. A researcher also checked participants' results weekly and initiate intervention if needed (e.g. medication changes, counselling) with the consent of the attending physician.

Standards for Reporting Qualitative Research (SRQR)*

<http://www.equator-network.org/reporting-guidelines/srqr/>

Page/line no(s).

Title and abstract

<p>Title - Concise description of the nature and topic of the study Identifying the study as qualitative or indicating the approach (e.g., ethnography, grounded theory) or data collection methods (e.g., interview, focus group) is recommended</p>	1
<p>Abstract - Summary of key elements of the study using the abstract format of the intended publication; typically includes background, purpose, methods, results, and conclusions</p>	3-4

Introduction

<p>Problem formulation - Description and significance of the problem/phenomenon studied; review of relevant theory and empirical work; problem statement</p>	6-7
<p>Purpose or research question - Purpose of the study and specific objectives or questions</p>	8

Methods

<p>Qualitative approach and research paradigm - Qualitative approach (e.g., ethnography, grounded theory, case study, phenomenology, narrative research) and guiding theory if appropriate; identifying the research paradigm (e.g., postpositivist, constructivist/ interpretivist) is also recommended; rationale**</p>	10
<p>Researcher characteristics and reflexivity - Researchers' characteristics that may influence the research, including personal attributes, qualifications/experience, relationship with participants, assumptions, and/or presuppositions; potential or actual interaction between researchers' characteristics and the research questions, approach, methods, results, and/or transferability</p>	10
<p>Context - Setting/site and salient contextual factors; rationale**</p>	9
<p>Sampling strategy - How and why research participants, documents, or events were selected; criteria for deciding when no further sampling was necessary (e.g., sampling saturation); rationale**</p>	9
<p>Ethical issues pertaining to human subjects - Documentation of approval by an appropriate ethics review board and participant consent, or explanation for lack thereof; other confidentiality and data security issues</p>	11
<p>Data collection methods - Types of data collected; details of data collection procedures including (as appropriate) start and stop dates of data collection and analysis, iterative process, triangulation of sources/methods, and modification of procedures in response to evolving study findings; rationale**</p>	9-10

1 2 3 4 5	Data collection instruments and technologies - Description of instruments (e.g., interview guides, questionnaires) and devices (e.g., audio recorders) used for data collection; if/how the instrument(s) changed over the course of the study	10-11 & Table 1
6 7 8	Units of study - Number and relevant characteristics of participants, documents, or events included in the study; level of participation (could be reported in results)	12
9 10 11 12	Data processing - Methods for processing data prior to and during analysis, including transcription, data entry, data management and security, verification of data integrity, data coding, and anonymization/de-identification of excerpts	10
13 14 15 16	Data analysis - Process by which inferences, themes, etc., were identified and developed, including the researchers involved in data analysis; usually references a specific paradigm or approach; rationale**	11
17 18 19 20	Techniques to enhance trustworthiness - Techniques to enhance trustworthiness and credibility of data analysis (e.g., member checking, audit trail, triangulation); rationale**	11

Results/findings

23 24 25 26	Synthesis and interpretation - Main findings (e.g., interpretations, inferences, and themes); might include development of a theory or model, or integration with prior research or theory	13-19
27 28 29	Links to empirical data - Evidence (e.g., quotes, field notes, text excerpts, photographs) to substantiate analytic findings	13-19

Discussion

32 33 34 35 36 37	Integration with prior work, implications, transferability, and contribution(s) to the field - Short summary of main findings; explanation of how findings and conclusions connect to, support, elaborate on, or challenge conclusions of earlier scholarship; discussion of scope of application/generalizability; identification of unique contribution(s) to scholarship in a discipline or field	20-22
38 39	Limitations - Trustworthiness and limitations of findings	22

Other

42 43 44	Conflicts of interest - Potential sources of influence or perceived influence on study conduct and conclusions; how these were managed	25
45 46	Funding - Sources of funding and other support; role of funders in data collection, interpretation, and reporting	25

*The authors created the SRQR by searching the literature to identify guidelines, reporting standards, and critical appraisal criteria for qualitative research; reviewing the reference lists of retrieved sources; and contacting experts to gain feedback. The SRQR aims to improve the transparency of all aspects of qualitative research by providing clear standards for reporting qualitative research.

**The rationale should briefly discuss the justification for choosing that theory, approach, method, or technique rather than other options available, the assumptions and limitations implicit in those choices, and how those choices influence study conclusions and transferability. As appropriate, the rationale for several items might be discussed together.
