Assessment of human diploid genome assembly with 10x Linked-Reads data --Manuscript Draft--

Manuscript Number:	GIGA-D-19-00092R1				
Full Title:	Assessment of human diploid genome assembly with 10x Linked-Reads data				
Article Type:	Data Note				
Funding Information:					
Abstract:	Background: Producing cost-effective haplotype-resolved personal genomes remains challenging. 10x Linked-Read sequencing, with its high base quality and long-range information, has been demonstrated to facilitate de novo assembly of human genomes and variant detection. In this study, we investigate in depth how the parameter space of 10x library preparation and sequencing affects assembly quality, on the basis of both simulated and real libraries. Findings: We prepared and sequenced eight 10x libraries with a diverse set of parameters from standard cell lines NA12878 and NA24385 and performed whole genome assembly on the data. We also developed the simulator LRTK-SIM to follow the workflow of 10x data generation and produce realistic simulated Linked-Read data sets. We found that assembly quality could be improved by increasing the total sequencing coverage (C) and keeping physical coverage of DNA fragments (CF) or read coverage per fragment (CR) within broad ranges. The optimal physical coverage was between 332X and 823X and assembly quality worsened if it increased to greater than 1,000X for a given C. Long DNA fragments could significantly extend phase blocks, but decreased contig contiguity. The optimal length-weighted fragment length ($W\mu_FL$) was around 50 – 150kb. When broadly optimal parameters were used for library preparation and sequencing, ca. 80% of the genome was assembled in a diploid state. Conclusion: The Linked-Read libraries we generated and the parameter space we identified provide theoretical considerations and practical guidelines for personal genome assemblies based on 10x Linked-Read sequencing. Keywords: 10x Linked-Read sequencing, de novo assembly, diploid human genome, library preparation

Response to Reviewers:	Reviewer reports: Reviewer #1: Zhang et al. explore the parameter space of 10X libraries and the subsequent effects of those parameters on de novo assembly performance. They also developed an in silico simulator and that generates results similar to experimental findings. The manuscript is well written and easy to understand.				

We thank the reviewer for these positive comments and address each point below.

That said, I think there are some analyses missing that should be included:

1. I think you should variant call off of the de novo assemblies to see if there are any differences you are missing because you're only looking at things at a very high structural level.

We have now called SNVs and SVs from our de novo assemblies and from other methods. Please find our results in the responses to points 2-4 of reviewer2.

2. How is phasing affected? I don't see any data on that other than total diploid regions. You should include the changes to the phase block N50. It's mentioned in the abstract, but I don't see it anywhere else.

We have showed the trend of phased block N50 in different linked-read sets in Figure S14, now we also provided the values of phase block N50s in Table S6

3. Besides NA50 you should include assembly errors such as breakpoints, translocations, inversions, relocations, etc..... You have a nice dataset here, you should try to get more out of it.

Thank you for the suggestions. We have re-run QUAST and generated several detailed statistics which are now shown in Table S4. These results are consistent with the contig N50s reported in Figure 3.

Minor comments:

58-66, Probably should add this reference for PacBio CCS sequencing, contig N50 is 15 mb, https://www.biorxiv.org/content/10.1101/519025v2 We have added this reference

65-66, I'd argue that this statement is a bit strong, cost is lowering, and throughput is increasing for these systems

This is now lines 70-72. We have rephrased the sentence and now write: "However, long-fragment sequencing suffers from extremely high cost (in the case of PacBio CCS), or low base quality (in the case of single-pass reads of either technology), hampering its usefulness for personal genome assembly."

68 Not a complete sentence We fixed this

Ref 27 isn't our stLFR paper, the doi for that is 10.1101/gr.245126.118, and it is commercially available now in some parts of the world We have added the new reference and deleted the confusing words in this sentence.

Reviewer #2: Zhang and co-authors present a parameter study for 10x linked-read sequencing experiments with the objective of evaluating the influence of experimentally controllable parameters on the final diploid assembly quality. The authors perform basic performance evaluation in terms of common metrics such as N50 values and provide technical recommendations for designing linked-read sequencing experiments. Additionally, Zhang et al. implemented a software tool for simulating linked-read sequencing data, which they use for parameter assessment given the known (simulated) truth.

While such studies that provide guidance to users of a sequencing technology are very valuable in principle, I have a number of concerns that should be addressed:

1. There is a closely related article by Luo et al. (2017, DOI:

10.1016/j.csbj.2017.10.002) that has been missed. The authors should clarify what the added value of their study is beyond the work by Luo et al. This comment applies to both aspects: guidance to users in terms of 10x sequencing experiments and the utility/features of their data simulation tool (note that Luo et al. also provide a simulator).

We appreciate and cite the work by Luo et al. However, our study provides (1) a more flexible simulation tool and (2) an extensive set of new sequence data.

Regarding (1)

A. We explicitly allow users to input CF, CR, W μ _FL and μ _FL, which have strong connections with library preparation and Illumina sequencing. For example, CF is driven by input DNA amount and μ _FL by DNA preparation and potential size selection. LRSIM only lets the user set the total number of reads.

B. The usability of LRTK-SIM is better than LRSIM. LRSIM requires many third party packages and software to be installed first, such as Inline::C perl library, DWGSIM etc. It is not convenient for the users with insufficient computer experience. LRTK-SIM was written in Python and no third-party software was required. It can be installed and gotten started easily. LRTK-SIM can parallel simulate multiple libraries with a variety of parameters simultaneously. The users can compare the performance of different parameters in one run.

Regarding (2)

Luo et al. compared the influence of different parameters by simulation only, which does not always reflect the situation in real sequencing. In our study, we prepared six real libraries with different parameters and could validate our observations from simulation data.

2. The focus of this manuscript is on guiding researchers who are after a cost-effective characterization of individual human genomes. In my view, Zhang et al. should go the full distance and additionally compare to standard Illumina sequencing followed by mapping and variant calling as a baseline. The assembly metrics employed are not so very informative when it comes to the question of which variation (relative to the reference genome) is been missed/captured in standard approaches.

While human assembly is the focus, we believe that much of the interest in our work will come mainly from researchers who are interested in assembling novel genomes. We use human as an assembly model because assembly quality can be gauged by comparison to the reference sequence. Nonetheless ...

Beyond comparing to standard Illumina sequencing, including a detailed comparison to reference-based processing of 10x data (e.g. using LongRanger) would be interesting. In this way, this study would by much more helpful for planning sequencing studies.

... in response to this comment, we now systematically investigate SNV and SV calls from our assemblies. We compare with standard Illumina data and reference-based processing of our 10x data. The standard Illumina data were downloaded from Genome In A Bottle and analyzed with SVABA to generate SV calls, and with BWA and FreeBayes to generate SNV calls. Long ranger was used to generate SNVs and SVs (only deletions) for 10x reference-based analysis. We noted that R9 failed to be analyzed by Long Ranger due to its extremely large CF. We compared SNV and SV calls among the different approaches using vcfeval

(https://github.com/RealTimeGenomics/rtg-tools) and truvari (https://github.com/spiralgenetics/truvari), respectively.

For SNVs, we compared the calls from three strategies to the gold standard of NA12878 (ftp://ftp-

trace.ncbi.nlm.nih.gov/giab/ftp/release/NA12878_HG001/latest/GRCh38/) and NA24385 (ftp://ftp-

trace.ncbi.nlm.nih.gov/giab/ftp/release/AshkenazimTrio/HG002_NA24385_son/latest/G RCh38/).

We found that SNVs from reference-based processing of Illumina and 10x data were comparable, and both of them were better than assembly-based SNV calls. For SVs, our assemblies generated many calls that were missed by the reference-based strategy.

We now provide several additional supplementary tables (Table S7-S12) to present these results.

3. The main reason (in my view) for pursuing de novo assembly of human genomes is to access structural variation that is missed otherwise. An evaluation on how much structural variation is (accurately) captured would be of interest to many readers. This is actually something that the authors point out in the Discussion themselves: "Arguably, the metric that matters most in the context of a personal genome is the discovery of variation that lower-cost approaches do not enable."

As implied by the quote, we agree with the reviewer's comment. Consequently, we now compare three linked-read sets from HG002 with the Tier 1 SV benchmark from Genome in a Bottle by using truvari (https://github.com/spiralgenetics/truvari). The results are summarized in Table S13.

4. PacBio CCS reads are available for HG002 (see Wenger at al., http://dx.doi.org/10.1101/519025). Mapping those CCS reads back to your diploid assemblies and calling variants provides an easy and powerful opportunity to assess the sequence quality from an independent technology.

These data became available while our manuscript was in review. We note that the PacBio CCS calls on HG002 are generally reasonably accurate but are not guaranteed to be correct in the absence of a gold standard. Therefore, we prefer to compare them in an overlap analysis with our calls, as opposed to implying that they are a gold standard by using the term "validation". We used vapor (https://github.com/mills-lab/vapor) to validate our SV calls based on PacBio CCS reads from HG002 and include Table S14 to show the validation rates.

Beyond this, your evaluation could be improved by also adding an assembly evaluation perspective that is more biologically motivated, e.g., number of recovered genes/disrupted genes or similar (this should be supported by Quast-LG/BUSCO).

We have added this analysis in Table S4.

Minor comments

- line 51: pedigree based phasing is quite powerful even for trios (where it is able to phase all variants that are homozygous in at least one individual), so I disagree to the statement that this is only feasible in large pedigrees. We fixed this and removed confusing words.

- lines 60ff: it is unclear which study your are referring to here, please add the citation at the end of the sentence (N50 31.1Mb) We included a new reference here.

 - line 68: broken sentence; also, putting the citation at the end of the sentence increases readability
 We fixed this issue.

- lines 71/72: again, unclear which study you are referring to ("Long Fragment Read") We included a new reference here.

- lines 125ff: is there a specific reason why five and three? (And not, e.g., five and five?) Also, the meaning of L, M, and H in the subscript of L should be explained Because we generated two additional libraries (L_1L and L_1M for NA12878) to evaluate the effects of CF and CR in assembly, and we believe the trend should be consistent in the two samples. L, M and H represent low, medium and high CF in the experiments. We have clarified this in the manuscript.

- line 129: percent of what? The percent of GEM in 10x Chromium system.

- line 151: please be more specific about which version of hg38 was used (detail once if identical hg38 was used throughout the rest of the paper [lines 165, 171, 195 and so on...])

The reference was downloaded from 10x website with the version of GRCh38

	Reference 2.1.0.
	 line 172: please provide an exact reference for the high confidence regions that you used (e.g., file URL) We have added the URL in the manuscript.
	- line 208: "in in" We fixed this.
	 line 208: this sentence is talking about real data, so the reference to Fig 2C and 2D does not match. We clarified this in the manuscript.
	 line 209: "but not dramatically []appreciably" - this is subjective language, please rephrase and be more fact-oriented (for instance by including the numbers you refer to in parentheses). We included the numbers and rephrased the sentence to be more fact-oriented.
	- line 250: "_Alignment" ? We fixed this.
	- line 251: what is the denominator for these 91% all bases that are not Ns in the reference genome? (Note that for this analysis, the version of hg38 matters, see comment above).
	 "N"s do not contribute to the denominator. The authors mention stLFR in line 278. There's a new preprint that's worth citing/discussing: http://dx.doi.org/10.1101/324392 We have cited their latest version.
	- line 296: "extremely long" please say what extremely long means here We defined "extremely long" as the DNA fragments longer than 200kb.
	- line 570: please be more specific what you mean by "in-house programs", and where the respective sources are available (is that the "Evaluate_diploid_assembly" github?) All the source codes for assembly evaluation are available in https://github.com/zhanglu295/Evaluate_diploid_assembly. We added this information in the sentence.
	- please add a - preferably open source - license file to your github repositories We added the license files in the GitHub.
	- "sample prep" is jargon and should be replaced by "sample preparation" (eg. line 41, but also elsewhere) We have updated all the "sample prep" to "sample preparation" in the manuscripts.
Additional Information:	
Question	Response
Are you submitting this manuscript to a special series or article collection?	No
Experimental design and statistics	Yes
Full details of the experimental design and statistical methods used should be given in the Methods section, as detailed in our Minimum Standards Reporting Checklist. Information essential to interpreting the data presented should be made available in the figure legends.	

Have you included all the information requested in your manuscript?

Resources

Yes

A description of all resources used, including antibodies, cell lines, animals and software tools, with enough information to allow them to be uniquely identified, should be included in the Methods section. Authors are strongly encouraged to cite <u>Research Resource</u> <u>Identifiers</u> (RRIDs) for antibodies, model organisms and tools, where possible.

Have you included the information requested as detailed in our Minimum Standards Reporting Checklist?

Availability of data and materials

Yes

All datasets and code on which the conclusions of the paper rely must be either included in your submission or deposited in <u>publicly available repositories</u> (where available and ethically appropriate), referencing such data using a unique identifier in the references and in the "Availability of Data and Materials" section of your manuscript.

Have you have met the above requirement as detailed in our Minimum Standards Reporting Checklist?

Assessment of human diploid genome assembly with 10x

 preparation

36 Data description

37 Introduction

38 The human genome holds the key for understanding the genetic basis of human evolution, 39 hereditary illnesses and many phenotypes. Whole-genome reconstruction and variant discovery, 40 accomplished by analysis of data from whole-genome sequencing experiments, are foundational 41 for the study of human genomic variation and analysis of genotype-phenotype relationships. Over 42 the past decades, cost-effective whole-genome sequencing has been revolutionized by short-43 fragment approaches, the most widespread of which have been the consistently improving 44 generations of the original Solexa technology [1, 2], now referred to as Illumina sequencing. 45 Illumina's strengths and weaknesses are inherent in the sample preparation and sequencing 46 chemistry. Illumina generates short paired reads (2x150 base pairs for the highest-throughput 47 platforms) from short fragments (usually 400-500 base pairs) [3]. Because many clonally amplified 48 molecules generate a robust signal during the sequencing reaction, Illumina's average per-base 49 error rates are very low.

50

51 The lack of long-range contiguity between end-sequenced short fragments limits their application 52 for reconstructing personal genomes. Long-range contiguity is important for phasing variants and 53 dealing with genomic complex regions. For haplotyping, variants can be phased by population-54 based methods [4, 5] or family-based recombination inference [6, 7]. However, such approaches 55 are only feasible for common variants in single individuals or when a trio or larger pedigree is 56 sequenced. Furthermore, highly polymorphic regions such as the HLA in which the reference 57 sequence does not adequately capture the diversity segregating in the population are refractory 58 to mapping-based approaches and require de novo assembly to reconstruct [8]. Short-read/short-59 fragment data are challenged by interspersed repetitive sequences from mobile elements and by 60 segmental duplications, and only support highly fragmented genome reconstruction [9, 10].

61

62 In principle, many of these challenges can be overcome by long-read/long-fragment sequencing 63 [11, 12]. Assembly of Pacific Biosciences (PacBio) or Oxford Nanopore (ONT) data can yield 64 impressive contiguity of contigs and scaffolds. In one study [13], scaffold N50 reached 31.1Mb by 65 hierarchically integrating PacBio long reads and BioNano for a hybrid assembly, which also 66 uncovered novel tandem repeats and replicated the structural variants that were newly included 67 in the updated hg38 human reference sequence. Another study [14] produced human genome 68 assemblies with ONT data, in which a contig N50 ~3Mb was achieved, and long contigs covered 69 all class I HLA regions. A recent whole genome assembly of NA24385 [15] with high quality 70 PacBio CCS reads generated contigs with an N50 of 15Mb. However, long-fragment sequencing 71 suffers from extremely high cost (in the case of PacBio CCS), or low base quality (in the case of 72 single-pass reads of either technology), hampering its usefulness for personal genome assembly.

73

74 Hierarchical assembly pipelines in which multiple data types are used as another approach for 75 genome assembly [16]. For example, in the reconstruction of an Asian personal genome, fosmid 76 clone pools and Illumina data were merged, but because fosmid libraries are highly labor intensive 77 to generate and sequence, this approach is not generalizable to personal genomes. The "Long 78 Fragment Read" (LFR) approach [17], where a long fragment is sequenced at high depth via 79 single-molecule fragmented amplification, reported promising personal genome assembly and 80 variant phasing by attaching a barcode to the short reads derived from the same long fragment. 81 However, because LFR is implemented in a 384 well plate, many long fragments would be 82 labelled by the same barcodes, making it difficult for binning short-reads, and the great 83 sequencing depth required rendered LFR not cost-effective.

84

An alternative approach is offered by the 10x Genomics Chromium system, which distributes the DNA preparation into millions of partitions where partition-specific barcode sequences are

87 attached to short amplification products that are templated off the input fragments. Because of the limited reaction efficiency in each partition, the sequencing depth for each fragment is too 88 89 shallow to reconstruct the original long-fragment, distinguishing this approach from LFR [18]. 90 However, to compensate for the low read coverage of each fragment, each genomic region is 91 covered by hundreds of DNA fragments, giving overall sequence coverage that is in a range 92 comparable to standard Illumina short-fragment sequencing while providing very high physical 93 coverage. Novel computational approaches leveraging the special characteristics of 10x 94 Genomics data have already generated significant advances in power and accuracy of 95 haplotyping [19, 20], cancer genome reconstruction [21, 22], metagenomic assemblies [23], and 96 de novo assembly of human and other genomes [24-26], compared to standard Illumina short-97 fragment sequencing. While the uniformity of sequence coverage is not as good as with PCR-98 free Illumina libraries, 10x Linked-Read sequencing is a promising technology that combines low 99 per-base error and good small-variant discovery with long-range information for much improved 100 SV detection in mapping-based approaches [22, 27], and the possibility of long-range contiguity 101 in *de novo* assembly [24, 26, 28].

102

103 Practical advantages of the technology include the low DNA input mass requirement (1ng per 104 library, or approximately 300 haploid human genome equivalents). Real input quantities can vary, 105 along with other factors, to influence an interconnected array of parameters that are relevant to 106 genome assembly and reconstruction. The parameters over which the experimenter has influence 107 are (Figure 1): i). C_R: average <u>C</u>overage of short <u>R</u>eads per fragment; ii). C_F: average physical 108 Coverage of the genome by long DNA Fragments; iii). *N_{F/P}*: Number of Fragments per Partition; 109 iv). Fragment length distribution, several parameters of which are used, specifically μ_{FL} : Average 110 Unweighted DNA <u>Fragment</u> Length and $W\mu_{FL}$: Length-<u>W</u>eighted average of DNA <u>Fragment</u> 111 Length. Note that several parameters depend on each other. For example, a greater amount of 112 input DNA will increase $N_{F/P}$; shorter fragments increase $N_{F/P}$ at the same DNA input amount 113 compared to longer fragments; less input DNA will (within practical constraints) increase C_R and 114 decrease C_F ; and their absolute values are set by how much total sequence coverage is 115 generated because $C_R \times C_F = C$.

116

117 Our goal in this study was to experimentally explore the 10x parameter space and evaluate the 118 quality of *de novo* diploid assembly as a function of the parameter values. For example, we set 119 out to ask whether longer input fragments produce better assemblies, or what the effect of 120 sequencing vs. physical coverage is on contiguity of assembly. In order to constrain the parameter 121 space, we first performed computer simulations with reasonably realistic synthetic data. The 122 simulation results suggested certain parameter combinations that we then approximated in the 123 generation of real, high-depth, sequence data on two human reference genome cell lines, 124 NA12878 and NA24385. These simulated and real data sets were then used to produce de novo 125 assemblies, with an emphasis on the performance of 10x's Supernova2 [24]. We finally assessed 126 the quality of the assemblies using standard metrics of contiguity and accuracy, facilitated by the 127 existence of a gold standard (in the case of simulations) and comparisons to the reference 128 genome (in the case of real data).

129

130 Library preparation, physical parameters and sequencing coverage

We made six DNA preparations that varied in fragment size distribution and amount of input DNA, three each from NA12878 and NA24385. From these, we prepared eight libraries, five from NA12878 and three from NA24385 (**Table S1**). To generate libraries L_{1L} , L_{1M} and L_{1H} (the subscripts *L*, *M* and *H* represent low, medium and high C_F, respectively), genomic DNA was extracted from ca. 1 million cultured NA12878 cells using the Gentra Puregene Blood Kit following manufacturer's instructions (Qiagen, Cat. No 158467). The GEMs were divided into 3 tubes with 5%, 20%, and 75% to generate libraries L_{1L} , L_{1M} and L_{1H} , respectively (**Figure S1-S3**). For the

138 other libraries, to generate longer DNA fragments ($W\mu_{FL}$ =150kb and longer, Figure S4-S8), a 139 modified protocol was applied. Two-hundred thousand NA12878 or NA24385 cells of fresh culture 140 were added to 1mL cold 1x PBS in a 1.5 ml tube and pelleted for 5 minutes at 300g. The cell 141 pellets were completely resuspended in the residual supernatant by vortexing and then lysed by 142 adding 200ul Cell Lysis Solution and 1ul of RNaseA Solution (Qiagen, Cat. No 158467), mixing 143 by gentle inversion, and incubating at 37°C for 15-30 minutes. This cell lysis solution is used 144 immediately as input for the 10x Chromium preparation (ChromiumTM Genome Library & Gel 145 Bead Kit v2, PN-120258; ChromiumTM i7 Multiplex Kit, PN-120262). Fragment size of the input 146 DNA can be controlled by gentle handling during lysis and DNA preparation for Chromium. The 147 amount of input DNA (between 1.25 and 4 ng) was varied to achieve a wide range of physical 148 coverage (C_{F}). The Chromium Controller was operated and the GEM preparation was performed 149 as instructed by the manufacturer. Individual libraries were then constructed by end repairing, A-150 tailing, adapter ligation and PCR amplification. All libraries were sequenced with three lanes of 151 paired-end 150bp runs on the Illumina HiSeqX to obtain very high coverage (C=94x-192x), though 152 the two with the fewest number of gel beads $(L_{1L} \text{ and } L_{1M})$ exhibited high PCR duplication rates 153 because of the reduced complexity of the libraries (Table S1).

154

155 Linked-Reads subsampling

The high sequencing coverage in the libraries allowed subsampling to facilitate the matching of parameters among the different libraries, for purposes of comparability; these subsampled Linked-Read sets are denoted R_{id} (**Figure 1**). We aligned the 10x Linked-Reads to human reference genome (hg38, GRCh38 Reference 2.1.0 from 10x website) followed by removing PCR duplication by barcode-aware analysis in Long Ranger[21]. Original input DNA fragments were inferred by collecting the read-pairs with the same barcode that were aligned in proximity to each other. A fragment was terminated if the distance between two consecutive reads with the identical

barcode larger than 50kb. Fragments were required to have at least two read pairs with the same
barcode and a length of at least 2 kb. Partitions with fewer than three fragments were removed.

165 We subsampled short-reads for each fragment to satisfy the expected C_R .

166

167 Generating 10x simulated libraries by LRTK-SIM

168 To compare the observations from real data with a known truth set, we developed LRTK-SIM, a 169 simulator that follows the workflow of the 10x Chromium system and generates synthetic Linked-170 Reads like those produced by an Illumina HiSeqX machine (Supplementary Information and 171 Figure S9). Based on the parameters commonly employed by 10x Genomics Linked-Read 172 sequencing and the characteristics of our libraries, LRTK-SIM generated simulated datasets from 173 the human reference (hg38), explicitly modeling the five key steps in real data generation. 174 Parameters in parentheses are from the standard 10x Genomics protocol: 1. Shearing genomic 175 DNA into long fragments (W μ_{FL} from 50kb to 100kb); 2. Loading DNA to the 10x Chromium 176 instrument (~1.25ng DNA); 3. Allocating DNA fragments into partitions which are attached the 177 unique barcodes (~10 fragments per partition); 4. Generating short fragments; 5. Generating 178 Illumina paired-end short reads (800M~1200M reads). LRTK-SIM first generated a diploid 179 reference genome as a template by duplicating the human reference genome (hg38) into two 180 haplotypes and inserting SNVs from high-confidence regions in GIAB of NA12878 (ftp://ftp-181 trace.ncbi.nlm.nih.gov/giab/ftp/release/NA12878_HG001/latest/GRCh38/HG001_GRCh38_GIA

182 B_highconf_CG-IIIFB-IIIGATKHC-Ion-10X-SOLID_CHROM1-

183 X_v.3.3.2_highconf_nosomaticdel_noCENorHET7.bed); For low-confidence regions we 184 randomly simulated 1 SNV per 1 kb. The ratio was 2:1 for heterozygous and homozygous SNVs. 185 From this diploid reference genome, LRTK-SIM generated long DNA fragments by randomly 186 shearing each haplotype with multiple copies into pieces whose lengths were sampled from an 187 exponential distribution with mean of μ_{FL} . These fragments were then allocated to pseudo-

188 partitions, and all the fragments within each partition were assigned the same barcode. The 189 number of fragments for each partition was randomly picked from a Poisson distribution with mean 190 of $N_{E/P}$. Finally, paired-end short reads were generated according to C_R and replaced the first 16bp 191 of the reads from forward strand to the assigned barcodes followed by 7 Ns. More information 192 about implementation can be found in **Supplementary Information**. From that diploid genome, 193 Linked-Read datasets were generated that varied in C_R , C_F and μ_{FL} (W μ_{FL}) (Table S2-S3). 194 Varying $N_{F/P}$ was only done for chromosome 19 because of the infeasibility of running Supernova2 195 on whole genome assemblies with large $N_{E/P}$; within practically reasonable values, $N_{E/P}$ does not 196 appear to influence assembly quality (Figure S10). In total, we generated 17 simulated Linked-197 Read datasets to explore the overall parameter space (Table S2-S3) and 11 to match the 198 parameters of the abovementioned real libraries (Figure 1).

199

200 Human genome diploid assembly and evaluation

201 The scaffolds were generated by the "pseudohap2" output of Supernova2, which explicitly 202 generated two haploid scaffolds, simultaneously. Contigs were generated by breaking the 203 scaffolds if at least 10 consecutive 'N's appeared, per definition by Supernova2. For the 204 simulations of human chromosome 19, we used the scaffolds from the "megabubbles" output. 205 Contig and scaffold N50 and NA50 were used to evaluate assembly quality. Contigs longer than 206 500bp were aligned to hg38 by Minimap2[29]. We calculated contig NA50 on the basis of contig 207 misassemblies reported by QUAST-LG [30]. For scaffolds (longer than 1kb), we calculated the 208 NA50 following Assemblathon 1's procedure [31] (Supplementary Information).

209

210 Genomic variant calls from diploid assembly

211 We compared single nucleotide variants (SNVs) and structural variants (SVs) from the diploid 212 regions of our assemblies with the ones from standard Illumina data and reference-based

213 processing of our 10x data. The standard Illumina data were downloaded from Genome in a Bottle 214 [32] and analyzed with SVABA [33] to generate SV calls, and with BWA [34] and FreeBayes [35] 215 generate SNV calls. Lona (https://support.10xgenomics.com/genometo ranger 216 exome/software/pipelines/latest/ what-is-long-ranger) was used to generate SNV and SV (only 217 deletions) calls for 10x reference-based analysis. We noted that R₉ failed to be analyzed by Long 218 Ranger due to its extremely large C_F. For SNVs, we benchmarked the calls from three strategies 219 the standard of NA12878 (ftp://ftpusing gold 220 trace.ncbi.nlm.nih.gov/giab/ftp/release/NA12878 HG001/latest/GRCh38/) NA24385 and 221 (ftp://ftp-trace.ncbi.nlm.nih.gov/giab/ftp/release/AshkenazimTrio/HG002_NA24385_

son/latest/GRCh38/). For SVs, we compared three linked-read sets (R₉, R₁₀, R₁₁) from HG002
with the Tier 1 SV benchmark from Genome in a Bottle [36] and used VaPoR [37] to validate our
SV calls based on PacBio CCS reads from NA24385 (Highly-accurate long-read sequencing
improves variant detection and assembly of a human genome). We compared SNV and SV calls
among the different approaches using vcfeval [38] and truvari [36], respectively.

227

228 Performance of diploid assembly: influence of total coverage Diploid assembly by Linked-229 Reads requires sufficient total read coverage ($C=C_{R\times}C_{F}$) to generate long contigs and scaffolds. 230 In this experiment, to explore the roles of both physical coverage (C_F) and per-fragment read 231 coverage (C_R), we first generated eight simulated libraries whose total coverage C ranged from 232 16x to 78x: four with C_R fixed and increasing C_F and four with fixed C_F , and increasing C_R (**Table** 233 **S2**). Contig and scaffold N50s increased along with increasing either C_F or C_R (Figure 2A and 234 **2B**). To investigate whether the trend was also present in the real datasets, we analyzed six real 235 libraries (three by varying C_F , and the other three by varying C_R ; Figure 1): as C increased, we 236 varied C_F and C_R independently by fixing the other parameter. Contig and scaffold N50s also 237 increased in these simulation (Figure 2C and 2D) and real linked-read sets (Figure 2E and 2F) 238 as a function of total coverage C. Contig lengths did increase a little (621.4kb to 758.1kb for 239 simulation; 110.7kb to 119.6kb for real data) when C was increased beyond 56X. Accuracy, which 240 we define as the ratio between NA50 (N50 after breaking contigs or scaffolds at assembly errors) 241 and N50 (Figure 2C and 2E), changed 18% for simulation and 7% for real data (587.5kb to 242 713.3kb for simulation; 97.1kb to 104.5kb for real data). For scaffolds in the real data sets, when 243 C increased from 48X (R_3) to 67X (R_4), both scaffold N50 and NA50 were significantly improved 244 (N50: 13.4Mb to 30.6Mb; NA50: 6.3Mb to 12.0Mb), but the accuracy dropped slightly from 46.6% 245 to 39.1%, which indicated that scaffold accuracy may be refractory to extremely high C (Figure 246 **2F**). These results indicated that assembly length and accuracy were comparable over a broad 247 range of C_F and C_R at constant C, which implied that assembly quality was mainly determined by 248 С.

249

250 Performance of diploid assembly: influence of fragment length and physical coverage. To 251 investigate if input weighted fragment length (as measured by $W\mu_{FL}$) influenced assembly quality, 252 we generated four simulated libraries (**Table S3**) with fixed C_F and C_R and a range of fragment 253 lengths (Figure 3A). Contig length decreased with increasing fragment length, a trend that was 254 also seen in six real libraries (Figure 3B; C=56X; R_6 to R_{11} in Figure 1). We then simulated 255 another six libraries with the same parameters as the real ones to explore the effects of physical 256 coverage at constant C=56x (Figure 3C). Contig lengths decreased as a function of increasing 257 physical coverage, a trend that is somewhat less clear in real data possibly due to confounding 258 other parameters such as fragment length (Figure 3D). The two linked-read sets with the worst 259 contig qualities in NA12878 (R_7) and NA24385 (R_{10}) also showed a significant increase of the 260 number of breakpoints (Table S4)

261

262 <u>Performance of diploid assembly: nature of the source genome.</u> Assembly errors may occur
 263 because of heterozygosity, repetitive sequences, or sequencing error. To illuminate possible

264 sources of assembly error, we performed simulations by generating 10x-like Linked-Reads as 265 above from human chromosome 19, and then quantified assembly error against these synthetic 266 gold standards. Removal of interspersed repeat sequences from the source genome resulted in 267 better contigs with no loss of accuracy in experiments by varying C_F , C_R and μ_{EI} (Figure 4A, 4C 268 and 4E) and better scaffolds only if C_R was above 1X (Figure 4D). Removal of variation had little 269 effect on contigs and only gave rise to longer scaffolds if C_R was above 0.8X (Figure S11), which 270 is difficult to achieve with real libraries. Finally, a 1% uniform sequencing error had no discernible 271 effect (Figure S12).

272

273 Performance of diploid assembly: fraction of genome in diploid state. While contiguity is an 274 important parameter for any whole genome assembly, evaluation of diploid assemblies 275 necessitates estimating the fraction of the genome in which the assembly recovered the diploid 276 state. To this end, we divided the contigs generated by Supernova2 into "diploid contigs", which 277 were extracted from its megabubble structures, and "haploid contigs" from non-megabubble 278 structures. Pairs of scaffolds were extracted as the two haplotypes from megabubble structures 279 if they shared the same start and end nodes in the assembly graph. Diploid contigs were 280 generated by breaking the candidate scaffolds at the sequences with least 10 consecutive 'N's 281 and were aligned to human reference genome (hg38) by Minimap2. The genome was split into 282 500bp windows and diploid regions were defined as the maximum extent of successive windows 283 covered by two contigs, each from one haplotype._Alignment against the human reference 284 genome revealed the overall genome coverages of the six assemblies to be around 91%. For 285 most assemblies, 70%-80% of the genome was covered by two homologous contigs (Table 1), 286 with R_6 only reaching 58.9%, probably due to the short fragments of the DNA preparation 287 (μ_{FL} =24kb). We also analyzed another seven assemblies produced by 10x Genomics, all of which 288 had diploid fractions of about 80% as well (Table S5). In the male NA24385, non-289 pseudoautosomal regions of the X chromosome are hemizygous and should therefore be

recovered as haploid regions. Between 79.9% and 87.6% of these regions were covered by one contig exactly depending on the assembled library. Library construction parameters other than fragment length appeared to have had little impact on the proportion of diploid regions (**Tables 1** and **Table S5**).

294

295 Overlapping the diploid regions from the assemblies of the same individual revealed that 50.24% 296 and 67.27% of the genome for NA12878 and NA24385 (Figure S13), respectively, were diploid 297 in all the three assemblies. NA12878 was lower because of the low percentage of diploid regions 298 in assembly R_6 (**Table 1**). The overlaps were significantly greater than expected by chance 299 (NA12878: 33.3%, p-value=0.0049; NA24385: 45.4%, p-value=0.0029. Chi square test). These 300 observations were consistent with heterozygous variants being enriched in certain genomic 301 segments, in which two haplotypes were more easily differentiated by Supernova2. Phase block 302 lengths were mainly determined by total coverage C and increased in real data with increasing 303 fragment length (Figure S14, Table S6).

304

305 Performance of diploid assembly: quality of variant calls. The ultimate goal of human genome 306 assembly is to accurately identify genomic variants. We compared the SNVs and SVs from our 307 assemblies with the calls from referenced-based processing of standard Illumina and 10x data, 308 and benchmarked them using gold standard from Genome in a Bottle and PacBio CCS reads. 309 We found the SNVs from referenced-based processing of standard Illumina and 10x data were 310 comparable and both of them were better than assembly-based calls (**Table S7** and **S8**) For SVs, 311 our assemblies generated many calls that were missed by the reference-based strategy (Table 312 S9-S12) and even by the Tier 1 benchmark of Genome in a Bottle (Table S13), and half of the 313 deletions and a majority of insertions could be validated by PacBio CCS reads (Table S14).

314

315 **Discussion**

In this study, we investigated human diploid assembly using 10x Linked-Read sequencing data on both simulated and real libraries. We developed the simulator LRTK-SIM to examine the likely impact of parameters in diploid assembly and compared results from simulated reads to those from real libraries. We thus determined the impact of key parameters (C_R , C_F , $N_{F/P}$ and $\mu_{FL}/W\mu_{FL}$) with respect to assembly continuity and accuracy. Our study provides a general strategy to evaluate assemblies of 10x data and may have implications for the evaluation of other barcodebased sequencing technologies such as CPTv2-seq [39] or stLRF [40] in the future.

323

10x Practicalities

325 For standard Illumina sequencing, library complexity is usually sufficient to generate tremendous 326 numbers of reads from unique templates and read coverage can be increased simply by 327 sequencing more. However, the 10x Chromium system performs amplification in each partition, 328 and generally only about 20% to 40% of the original long fragment sequence can be captured as 329 short fragments and eventually as reads, resulting in shallow sequencing coverage per fragment. 330 Sequencing more deeply does not increase the per-fragment coverage much as most of the extra 331 reads are from PCR duplicates. The solution is to sequence multiple 10x libraries constructed 332 from the same DNA preparation and merge them for analysis. This means that C_{R} remains in the 333 standard range where PCR duplicates are relatively rare, but C_F increases proportionally to the 334 number of libraries used. A practical limitation to this approach is that Supernova2 limits the 335 number of barcodes to 4.8 million.

336

Our results showed that in practice, C_F should be between 335X and 823X, but no larger than 1000X, given the optimal coverage of *C*=56X recommended by 10x and the requirement for sufficient per-fragment read coverage. Surprisingly, we observed that including more extremely

long fragments was detrimental for assembly quality. This is possibly due to the loss of barcode specificity for fragments spanning repetitive sequences. From a computational perspective, too many long fragments are harmful to deconvolving the *de bruijn* graph, as more complex paths need to be picked out. In our experiments, $W\mu_{FL}$ between 50kb and 150kb is the best choice to generate reliable assemblies.

345

346 **Parameters driving assembly quality**

347 Our results regarding assembly quality, and the 10x parameters that influence it, may be useful 348 for efforts in which de novo assemblies are important for generation of an initial reference 349 sequence. We show that maximization of N50 does not necessarily reflect assembly quality, 350 which we were able to compare to NA50 because there exists a high-quality human reference 351 genome. Contig and scaffold lengths mostly increased with ascending sequencing coverage, and 352 at sufficient overall sequence coverage it did not matter much whether the increasing coverage 353 C was accomplished by increasing C_R or C_F . However, both contig and scaffold accuracy 354 decreased with increasing C. We also found, counterintuitively, that contig and scaffold length 355 mostly decreased with increasing fragment length, a phenomenon that may be due to the specific 356 implementation; however, until there is another assembler that can be compared to Supernova2 357 it will not be possible to reason about this effect. In addition, intrinsic properties of the genome 358 matter greatly, as removal of repeats or lack of variation dramatically improves assembly quality.

359

Diploid assembly is the appropriate approach for assembly of genomes of diploid organisms that harbor variation. Therefore, an important metric to evaluate diploid assembly is the fraction of the genome that is assembled in a diploid state. The short input fragment length of R_6 resulted in roughly 20% less of the genome in a diploid state (<60% vs <80%) compared to the other libraries of the same individual. This observation suggests that in addition to metrics such as N50,

365 evaluation of assembly quality should also include the fraction of the genome (or the assembly)366 that is in a diploid state.

367

368 **Cost-benefit analysis**

369 Overall, we have attempted to give practical guidelines to assembly of 10x data with Supernova2 370 and evaluate the performance across a wide range of metrics. Arguably, the metric that matters 371 most in the context of a personal genome is the discovery of variation that lower-cost approaches 372 do not enable. We estimate that the cost increase over standard Illumina sequencing is about 2x, 373 given the 10X preparation cost and the higher level of sequence coverage required. There may 374 be many applications for which this combination of excellent single nucleotide variant detection 375 (via barcode-aware read mapping) and precise structural variant discovery (via assembly), 376 achieved by the same data set, is worth the price.

377

378 **Comparison with hybrid assemblies**

379 Hybrid assembly strategies have been applied successfully to produce human genome assembly 380 of long contiguity [13, 14, 41]. In these studies, long contigs are first produced by single-molecule 381 long-reads, such as PacBio (NG50=1.1Mb; [13]) or Nanopore (NG50=3.21Mb; [14]) comparing 382 favorably to our best results for Linked-Reads assemblies (NG50=236kb). Scaffolding is then 383 performed with complementary technologies such as BioNano to capture chromosomal level long-384 range information. It promoted the scaffold N50 of PacBio to 31.1Mb [13] and Illumina mate-pair 385 sequencing with 10x data to 33.5Mb [25]. Using SuperNova2, the scaffold N50 from our studies 386 reached ~27.86Mb (R_6) on the basis of 10x data alone, suggesting that 10x technology gives 387 broadly comparable results at a fraction of the price of long-read-based hybrid assemblies.

502 **Figure 1.** The linked-read sets prepared to evaluate the impact of C_{F} , C_{R} , μ_{FL} and $W\mu_{FL}$ on 503 human diploid assembly.

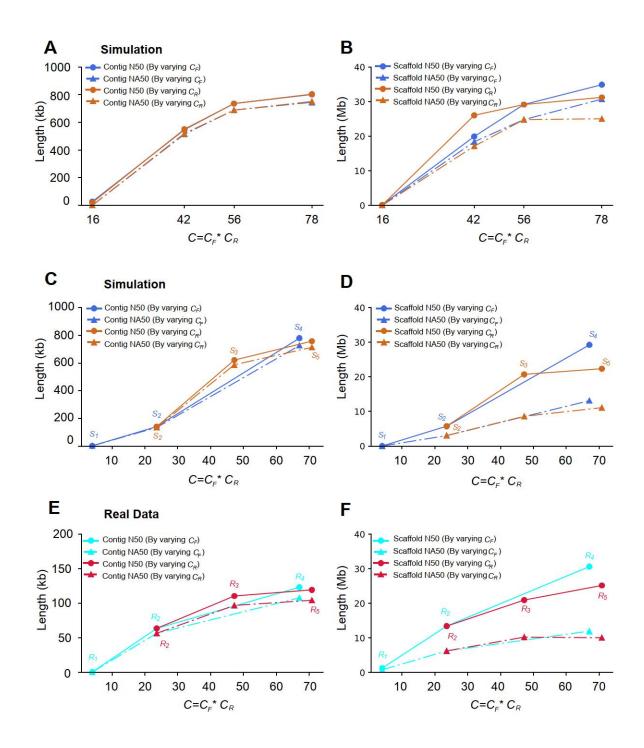

Figure 2. Contig and scaffold lengths (N50 and NA50) as a function of C_F or C_R . A and B: Simulated Linked-Reads with predefined parameters (**Table S2**); **C** and **D**: Simulated Linkedreads with matched parameters of real Linked-Read data sets (**Figure 1**); **E** and **F**: Real linkedread sets (**Figure 1**).

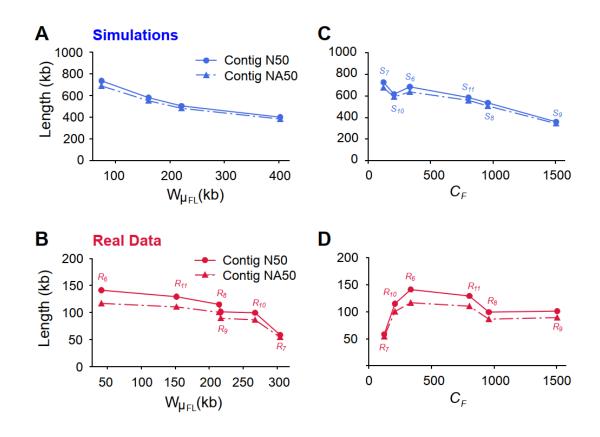

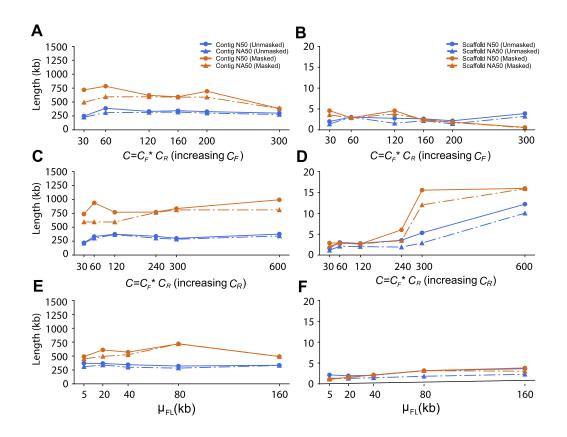

Figure 3. Contig qualities (N50 and NA50) as a function of fragment length $W\mu_{FL}$ or physical

511 coverage C_{F} , at C=56X. A and C, results from simulations; B and D, results from real data.

512

Figure 4. Comparison of contig and scaffold lengths from 10x data with masked and unmasked repetitive sequences by changing C_F , C_R and μ_{FL} . C_R was fixed to 0.2X in **A** and **B**; C_F was fixed to 300X in **C** and **D**; C_R was fixed to 0.2X and C_F was fixed to 300X in **E** and **F**.

Stanford, August 7, 2019

Dr. Hongling Zhou Editor GigaScience

Dear Dr. Zhou,

It is my pleasure to resubmit our revised, significantly improved and extended, manuscript "Assessment of human diploid genome assembly with 10x Linked-Reads data" for your further consideration for publication in GigaScience. We were able to address all of the reviewers' comments, which are addressed point by point in our response, and hope that you will be able to reach a positive decision.

Sincerely,

over a hodow

Arend Sidow, Ph.D. Professor of Pathology and of Genetics SUMC R353 Stanford, CA 94305-5324
